# LIQUID-GAS FLOW IN VENTURI METER AND SHARP EDGED ORIFICE

BY

FRANK J. CHWALEK

### A THESIS SUBMITTED TO THE FACULITY OF THE DEPARTMENT OF CHEMICAL ENGINEERING OF NEMARK COLLEGE OF ENGINEERING

### IN PARTIAL FULFILLMENT OF THE REQUIREMENTS FOR THE DEGREE

OF

MASTER OF SCIENCE IN CHEMICAL ENGINEERING

NEWARK, NEW JERSEY

8678-51-61

### ABSTRACT

The results of a study of pressure drops across a 5/32 inch throat venturi meter and a 5/32 inch thin plate sharp-edged orifice for the horizontal cocurrent, flow of the air-water two-phase twofluid system in a 3/4 inch pipe under essentially isothermal conditions, are presented. This is the first critical study of two phase flow in a Venturi meter and in a  $5/32^{\circ}$  orifice.

Flows of water of 0.1 to 1.7 gallons per minute with air rates in range of 0.00022 lbs/sec. to 0.0092 lbs/sec. of air mixed in were studied. All flows were turbulent when judged with the conventional Reynolds number criteria. It was found that two phase two fluid flow in this region was not steady but fluctuated.

Predicted pressure drops calculated with the Chenoweth-Martin Correlation (1) gave results which were 50% to 150% too high for the orifice. An improved correlation is presented which gives predicted pressure drops to within 15% of the actual results for 85% of the data calculated, for both the orifice and the Venturi.

It is shown that temperature has important influence on single phase water flow in venturi, a 10% increase in pressure drop being observed with temperature rise in tap water from  $10^{\circ}$ C to  $40^{\circ}$ C.

### PREFACE

This thesis is the result of interest developed through two phase two fluid flow studies at the Newark College of Engineering Advanced Unit Operations Laboratory.

Work done by Martinelli (2), and simplified by Bergelin (3) indicated that an empirical method for estimating liquid-gas mixture pressure drops in a Horizontal pipe line system was possible.

It was decided to study the problem, using a controlled and well established medium for flow measure and pressure drop. The venturi meter and orifice were selected as this media.

Alves (4) re-studied the work of Martinelli and presented an inconclusive pressure drop study across for a return bend and a tee, with openings in a vertical plane.

Chenoweth and Martin (5) proposed an improved correlation encompassing values, fittings and an orifice, using standard friction coefficients for the fittings.

Their data were published during the preliminary investigations on this thesis.

(2) Ref. 5 (3) Ref. 4 (4) Ref. 11 (5) Ref. 10

The apparatus for this thesis was designed, constructed and operated by the Writer at the Newark College of Engineering.

The writer wishes to thank Professor G.C. Keefe for his guidance in this project and Mr. Furmadge of the Operations Laboratory for his assistance in the construction of the apparatus.

#### INTRODUCTION

This thesis was undertaken to study the isothermal flow of a two-phase two-fluid system across a venturi and an orifice, with the purpose of developing a correlation to predict more accurately actual pressure drops.

Air and water were selected as the fluids to be studied. Nitrogen and carbon dioxide were considered for study but these were not pursued; it was felt that the molecular weight of Nitrogen and its physical characteristic were close enough to that of air to not make its study significant. Data, to date, on the air-water system gives reproducibility to only 50%. Carbon dioxide posed a solubility problem which would remove the study from the reals of "mixtures".

Equipment was installed to permit any liquid to be used, especially to study effects of surface tension, but the work was beyond the scope of this thesis.

Martinelli (2) originally proposed an empirical correlation for the estimation of pressure drops for a two-fluid two-phase mixture in a Horizontal pipe and his results were presented by Bergelin (3) as "more usable" data. His correlation gave reproducibility of +20%and -50% in Horizontal  $l_2^{1*}$  pipe when the overall average pressures were low, that is in the neighborhood of 18 PSIA. The use of his method involves the calculation of a parameter X which involves the

(2) Ref. 5 (3) Ref. 4

ratio of the pressure drop of the liquid to that of the gas, each pressure drop being calculated as if the fluid were flowing alone in the system. These pressure drops are calculated by the standard Reynolds number & Fanning Equation theory but are modified by factors which are obtained from empirical data obtained by Martinelli. These factors are dependent of flow characteristics of the fluids and are determined by a study of the Reynolds Numbers of the individual fluids. The two phase pressure drop is determined from parameter  $\phi$  which is obtained from a plot of  $\phi$  vs. X.

Experiments in this laboratory indicate the above correlation for air-water flow in  $\frac{1}{2}^n$  pipe agrees within the limits of experimental accuracy as noted.

Alves (4) in 1954 presented his work on 1" pipe which bore out the results as obtained by Martinelli.

The standard return bend and side flow through a "Tee" are discussed briefly for the above fittings, published values of pressure drops expressed as equivalent lengths of pipe, hold for two phase two fluid flow, for the limited cases studied. It is pointed out, however, that his results are inconclusive in this respect. One of the chief difficulties lying in the fact that the fittings lay in a vertical plane - the differences in static head being mathematically corrected.

(4) Ref. 11

2

The results for pressure drops in straight pipe flow agree, within experimental accuracy, with those of Bergelin.

Alves presents an excellent physical and pictorial description of the "types" of flow encountered in his two phase air-water system, i.e. bubble, plug, stratified, wavy, slug, annular, and spray flows.

Chenoweth and Martin (5) present the latest (October 1955) work on two-phase two-fluid system pressure drops, an improved correlation being presented for test sections of  $l_2^{1/2}$  and 3" pipe size as well as a 3" globe valve, 3" long radius return bend, and, of greatest interest to this thesis, a sharp edged orifice of dismeter ratio 0.55. Apparetus used by Chenoweth was essentially the same as that of Martinelli and Alves. However, where Martinelli limited his studies to a maximum of 50 FSIG and 1" pipe, Chenoweth worked with  $l_2^{1/2}$  and 3" pipe for pressures up to 160 FSIA. It was noted that the Martinelli correlation gave calculated results up to 250% too high for 3" pipe and 100 FSIA.

For turbulent flow Chenoweth offers an improved empirical correlation, which tends to correct for pressure. The correlation is a plot of two phase pressure drop divided by a fictitious all liquid pressure drop versus the Liquid Volume Fraction with the ratio of the fictitious "all gas" to the fictitious "all liquid" pressure drop for the system as a parameter. Figure 8 shows their complete correlation. Using the Chenoweth correlation, the average of absolute deviations is 19% for  $1\frac{1}{2}$ " and 3" Horizontal pipes, for turbulent flow.

(5) Ref. 10

Chenoweth treats fittings by using the single phase friction coefficient for the fitting, as suggested by the Hydraulic Institute in 1948 (6). Inspection of Figure 8 shows that the parameter is reduced to the ratio of the specific gravities of the fluids at the test section, simplifying the calculations for orifice and Venturi alike.

The work presented in this thesis studies the air-water system through a test section of  $3/4^{\circ}$  pipe and a specially designed standard orifice and venturi meter, each having a nominal throat diameter of 5/32 inch. Flows of water varied from 0.1 to 1.7 GPM, being mixed with from 0.00022 to 0.0092 lbs/sec. of air. Throat pressures varied from 2 to a maximum of 30 PSIG. These ranges were selected to give a complete range of pressure drops of up to 50 inches of mercury; and the Venturi and orifice diameter of 5/32-inch was, by design, most suitable for producing the suitable pressure drops with available laboratory equipment. The design of the equipment proved to be very satisfactory for the study undertaken.

A literature survey was made on the "Pease Anthony" Venturi scrubber inasmuch as pressure drop across a Venturi scrubber are a measure of its efficiency (7). All references indicate a flow rate of from 2 to 6 GPM of water per 1000 CFM of air with a 9 to 15 inches of water pressure drop.

(6) Ref. 12 (7) Ref. 1, 15, 16, 17 & 18

Considerable work has been done on two phase single fluid flow in orifices and to a lesser extent in venturies.

(See Ref. 21, 22, 23, 27, 30.). Monroe (11) has developed an equation for relationship among a series of knife-edged orifices for the following variables: mass flow, viscosity, temperature, density, and pressure drop across all the orifices.

The most important system for single fluids is steam and water and much work has been done in this direction for steam trap design, boiler design and related equipment.

### 4-0

# (11) Ref. 27

### EQUIPMENT

The equipment was designed and installed strictly in accordance with Figure 1 and the Equipment Schedule which is part of Figure 1. It is to be noted that three test sections were available, Test Section V for all Venturi runs, Test Section 0, for runs 19 through 22, and Test Section  $O_2$  for all other orifice runs. Pressure taps for Venturi and Orifice were standard, as indicated in Figures 2 and 3 except for Test Section  $O_2$  which had pressure taps 38 pipe diameters up and downstream of orifice as shown in Figure 1.

The temperature, pressure, and pressure drop measuring instruments are labeled to conform to match the calculated and uncalculated data columns in Tables 2 and 3, except for rotameter readings  $R_A$  and  $R_W$ which are obviously for air and water and are tabulated in Column 4 and 8, respectively, in Table 2.

Water Rotameter "L" was calibrated and found correct to  $\pm .05$ G.P.M.; pressure gages were checked to maximum of 50 inches of mercury and were correct to  $\pm .5$  PSIG, the maximum deviation occurring below 5 PSIG.

#### EQUIPMENT SCHEDULE

- A Pressure Reducer, Foster Engineering Company #567030, 1/2",
   10 SCFM air from 90 PSIG to 45.
- B Safety Valve, Lunk. 629, 1/2" Bronze, Set at 45 PSIG, when used.
- C Temperature Indicator, glass laboratory thermometer, range -10-0-60°C.
- D Compound Gage, Ashcroft 1010, range -30-0-60 PSIG; 3 1/2" Dial
- E Fischer and Porter Company, SCFM Air Meter @ 14.7 P.S.I.A. and 70°F., Range 0.3 to 3.5, Serial No. W5=1326-2
- F Fischer and Porter Company, SCFM Air Meter @ 14.7 P.S.I.A. and 70°F., Range 0.1 to 1.2, Serial No. N5-1326-1
- G Schutte Koerting Syphon Fig. 217, 1/2" Size, Bronze, Capacity 270 GPH at 40 PSIG, 1 Ft. Suction and 20 Ft. Discharge
- H Schutte Koerting Water Jet Eductor, Fig. 264, 1/2" Size, Bronze, Capacity 127 GPH Water @ 10 PSIG Pressure, O Suction, O Discharge
- J Liquid Pump, Oberdorfer, 1/2" x 1/2" Bronze, Capacity, by Lab test, approx. 4 GPM @ 40 PSIG
- K Pressure Gage 0-120 PSIG
- L Rotameter, Brooks Type I Serial 399, 0.1 to 1.7 GPM of 1.0 Sp.

Gravity fluid, Tube Size R-8M-25-2. (For water service)

- M Venturi Tube See Figure 2 (For Test Section V, in Figure 1) -5/32" Throat with standard Venturi Angles.
- N Manometer, Miriam, Type W, Model M-100, Serial C-14941, Range 50 inches
- 0 Orifice, See Figure 3 (For test sections O<sub>1</sub> & O<sub>2</sub> in Figure 1) Approximately 9/64, sharp edged.
- Q Globe Valve

### PROCEDURE

The operation of the apparatus, as shown in Figure 1, was successfully done by always keeping a positive water pressure on the system, i.e. keeping air out of the manometer taps.

A constant flow of water, 1.0 GPM for example, was maintained through water rotameter - L and flow of air through the rotameters E(or F) was varied by controlling globe value Q. Pressure was adjusted at regulator A to keep P<sub>1</sub> at a constant pressure. Jet-G was designed to be used for high air flows and low water flows; and Jet-H for high water flows and low air flows. In practice it was found that jet selection was not critical.

Pressure downstream to the test sections was controlled by valves at the discharge.

It is of note that several minutes were required for each reading\_manipulate the equipment and approach reproducable conditions. A study of the data in Tables 2 and 3 will indicate that many single phase, water test runs were made to check and re-check reproducibility. However, once the system was properly freed of trapped air pockets, by vents not shown in Figure 1, very little trouble was experienced from the equipment and water alone always gave very reproducable results.

No temperature control was attempted, other than permitting equipment to reach "steady" condition.

### RESULTS

The data obtained are presented in Tables 1, 2, and 3. Table 2 includes laboratory data for which calculations were made, Table 3 includes only data for which no calculations were made. Inspection of the data in Table 3 indicates reasonable reproducability. Data were selected for calculation at random, to give a complete range of coverage.

Single phase water-flow vs. temperature of water are plotted in Figure 4.

Figure 5 incorporates single phase pressure drop versus water flow calculated using standard formulae for orifice and venturi and actual experimental results.

Figures 6 and 7 are plots of water flow rate versus pressure drop at all air flows studied.

Figure 14 is a plot of water flow versus pressure drop as obtained experimentally and used in calculations for determining the "all liquid" pressure drop.

Figure 15A and Figure 15B are the plotted predicted pressure drops versus actual pressure drops.

Note that each of the Figures 15A and 15B indicates a correction equation for modifying the predicted result to give the actual pressure drop within 15% (approximate) accuracy for 85% of the data plotted.

### DISCUSSION

In initial runs while the equipment was being tested, it was observed that here was a marked increase in pressure drop across the venturi with an increase in temperature. A study of Figure 4 shows grouping of data when temperature of the water was in the range of 12 to  $22^{\circ}$ C, but a further increase in temperature to  $40^{\circ}$ caused a 10% increase in pressure drop.

These data were plotted from runs where <u>warm</u> tep water was run through Test Section-V, during start up and continued as the tap water cooled to outside (winter) conditions.

The grouping of the data at the lower temperatures is explained by the fact that runs were made on different days when solubility of air in water probably varied. Variations in the low temperature group was about 2 to 3%.

Figure 5 shows the comparison of calculated pressure drops of single-phase water flow in the venturi and in the orifice as well as experimental results. The curves for the venturi coincided; the curves for the orifice did not. The orifice deviation is explained by the fact that the unit was "home-made" and subject to the calibration curve for laboratory use. Figure 5 served as a calibration curve for the orifice for subsequent calculations.

Figure 5 is a plot of Table 5, the orifice calculations being obtained from these values, corrected, for orifice coefficients.

The experimental curves were plotted from data for single phase runs.

The results are shown to be within limits of experimental error by studying Figures 6 and 7, which show water flow rate in G.P.M. versus pressure drop at various flow rates of air expressed in pounds per second. Each of the points plotted is accompanied by a flow rate of air noted with it. Curves have been drawn to indicate a parameter,  $R_A$ , of air rates. Inassuch as the figures are plotted on regular linear graph paper, the resulting curves are accurate enough for approximating pressure drops for the air-water system at pressures up to 30 PBEG, with about 20% accuracy. Because data for pressure drops across the orifice were more limited, the Venturi plot, Figure 6, is more usable. Figures 6 and 7 were primarily used to check for reproducability of runs.

The Chenoweth-Martin (5) correlation is best represented by Figure 8 which has been reproduced from their data and used for calculations in this thesis.

Figures 9, 10, 11 and 13 are nonographs used in reducing the data to usable terms. Figure 9 was used to obtain the density of air at the test sections and results are tabulated in Table 2 Column 6. Figures 10 and 11 gave the air rate expressed in lbs./sec.; the results are plotted in Column 5. Figure 13 converted GPM of water to lbs./sec.; results are tabulated in Column 9.

Figure 12 has been plotted to show the values of Friction Coefficients, K, for Orifices and Venturi sections, for various area ratios. Inasmuch as the values for the test orifice and venturi of this thesis lay on the extrapolated curve, the K factor was <u>not</u> used, (nor was it required).

Inassuch as the 1948 Edition of the Hydraulic Institute Hydraulic Data were not available, the values suggested by Addison (9) have been plotted.

Figure 14 is essentially the same data as in Figure 5 for experimental results, plotted to give a more usable graph. Orifice run 19 is for Test Section  $O_1$ ; orifice run 27 is for test section  $O_2$ . This fig. was used to obtain  $\triangle P_L^*$  which is the pressure drop calculated assuming total mass flow to be water, as tabulated in Table 2, Column 21, from the total flow in Column 16. In effect Figure 14 is the calibration curve for the venturi and orifice. The liquid volume fraction, LVF, is the ratio of liquid volume to total volume flow. Column 19 is the ratio of water density to density at the test section conditions.

Figures 15A and 15B is the plot of actual pressure drop as obtained experimentally,  $(\Delta P_2 \text{ or} \Delta P_3)$  versus the two phase pressure drop,  $(\Delta P_{TP})$ , as obtained from the Chenoweth Martin correlation (Physically, multiplying columns 20 and 21 in Table 2). The plotted points on Figure 15-B for the orifice, are comparable in grouping to

(9) Ref. 14

those of Chenoweth and Martin (1) and the results are at least as consistent. This is of interest because the diameter ratio of their orifice was 0.55 while the orifice of this thesis is 0.19.

(1) Ref. 10 p.154

FIGURE -14 10 1. WATER, LBS/SEC VS AP. INS. Hg. ACROSS VENTURI & ORIFICE VENTURI 50" THROAT WATER From IN LES/SEC ORIFICE SAL SHARP EDGE ORIFICE RUN 27 VENTURI RUN Ð WATER FLOW IN ت ، • Ì 5/1/56 N.C.E. . \*\* 2 ì AP INS HG MANOMETER REAPING

A straight line drawn through the orifice experimental data of this thesis as plotted in Figure 15B permits a logarithmic equation:

(1)  $\triangle P_{\text{TP ACT}} = 0.22 (\triangle P_{\text{TP PRED}})^{1.17}$ 

where  $(\Delta P_{TP ACT})$  is the proposed predicted pressure drop of this thesis and  $\Delta P_{TP PRED}$  is the Chenoweth-Predicted Value.

Figure 15-A is a similar plot for the venturi, which has no counterpart in recent literature. A similar expression is developed for the venturi:

(II)  $\triangle P_{\text{TP ACT}} = 0.40 (\triangle P_{\text{TP PRED.}})^{1.17}$ 

With the terms defined as above. The equations are developed on Figure 15A and 15B. It is of much significance that the slopes of the straight line curves plotted are the same, within experimental accuracy, and both expressions correct the predicted value to read within 17% of the actual pressure drops for about 85% of the data. It is concluded that the above correllation, as expressed in equation form, when used with the Chenoweth-Martin correlation gives a more satisfactory estimation of pressure drops under conditions of flow of this thesis.

From the Chenoweth-Martin plot a similar expression can be derived. A curve drawn through their data indicates an expression;

(III)  $\Delta P_{\text{TP ACT}} = 0.45 (\Delta P_{\text{TP PRED.}})^{1.17}$ 

Because the exponent of the ( $\Delta P_{TP \ PRED}$ ) term is exactly the same it is suggested that the following general form of the equation

is possible for venturis and orifices:

Ŷ

(IV)  $\triangle P_{\text{TP ACT}} * K' (\triangle P_{\text{TP PRED}})^{1.17}$ 

Where K<sup>1</sup> would be a constant for a given orifice or venturi in twophase two fluid flow, depending on throat and pipe diameters. In Word form, "Predicted two phase pressure drop equals a constant, K', times the 1.17 power of predicted two phase pressure drop as predicted by Chenoweth".

It is noted that two-phase two-fluid flow is an <u>unsteady</u> state flow as evidenced by fluctuations in manometer and pressure readings. Dampening pressure lines permitted readings to be taken.

Pressures of air had to be raised from 30 to 50 PSIG to exceed the stability curve minimum of 45 PSIG for the air rotameter. The increase in pressure did not materially affect the "unsteady state" condition.

Because the Reynolds number did not vary appreciably, the 10% change in two phase pressure drop was attributed to the change in solubility of air in water (see Figure 4) where temperature varied from  $10^{\circ}$ C to  $40^{\circ}$ C. The change in surface tension, viscosity, velocity, and gravity were not sufficient to cause the marked change.

FIG. 15-A

#### CONCLUSIONS

It is concluded that for turbulent air and water flow through a venturi or orifice meter:

(1) Pressure drops can be predicted to within 15% - the best previous correlation treats the orifice only and give results from with deviations from 50% to 250%.

(2) The use of the following equation is possible for predicting pressure drops to within 15%: for <u>both</u> orifice and venturi:

 $\Delta P_{TP}$ , (Predicted) = K' ( $\Delta P_{TP}$ ') 1.17

where  $\triangle P_{TP}$ ' is the predicted pressure drop of Chenoweth and Martin for an orifice and K' is a constant depending on disaster ratios.

(3) Pressure drops are affected markedly by temperature changes and that these changes are not attributable to changes in the Reynolds' number. Solubility of gases in a fluid, surface tension, velocity, surface phenomena, and other variables such as the flashing of liquids affect pressure drops to a much greater extent in the two phase two fluid systems than in single phase or in single fluid systems.

### RECOMMENDATIONS

Beyond the scope of this thesis, the following are suggested as avenues for further work on two-phase two-fluid flow.

1. Investigation of the effect of surface tension (The WEBER number) on pressure drops in the Venturi. Pardoe (10) indicates a variation of over 1/23 in the Fanning Friction Factor, f, due to the effect of ambient temperature, for single phase flow. This indicates that the friction factor is not a function of the Reynold's Number and a roughness factor alone.

2. Noody<sup>(10)</sup> also suggests that the friction factor may be affected by the MACH or CAUCHI which introduce acoustic velocity, and FROUDE'S number which considers "Free surface" phenomena. The orifice and venturi coefficients may be a function of these variables.

The apparatus is well suited to these possible investigations.

# TABLE 4

# NOMENCLATURE

A	٠	cross-sectional area of pipe, square fest
D	٠	pipe diameter, feet
t	*	friction factor for Fanning equation, dimensionless
ß	*	acceleration constant due to gravity, ft/sec2
Ģ	•	mass flow rate, 1b (mass)/sec ft <sup>2</sup>
x		friction coefficient for a valve or fitting, dimensionless
L	÷	length of pipe, feet
Re	*	Reynolds mamber, dimensionless
W	*	flow rate of fluid, 1b (mass) /sec
∆₽	*	pressure drop, 1b (force)/ft <sup>2</sup> , or In.H <sub>g</sub> , where applicable
4	٠	viscosity, 1b (force)/ft sec
e	*	density, 1b (mass)/ft <sup>2</sup>
¢	٠	ratio $(\Delta P_{\rm TP} / \Delta P_{\rm SP})^2$ dimensionless
		Ordinate for Lockhart and Martinelli correlation
X	٠	ratio (P1/Pg, dimensionless
		Abscissa for Lockhart and Martinelli correlation
¥	۲	dimensionless group equal to $\frac{f1}{D} \neq K$
٧٥	•	orifice velocity, ft/sec., average
V1	۲	velocity, upstream to orifice, ft/sec, average
Hy	۲	static head difference between upstream and Vena Contracta in ft.
e	*	contraction coefficient, dimensionless
u	٠	velocity, ft/sec

- T temperature, °C
- P pressure, PSIG or Ins.H.
- Ra air flow, #/sec., ft<sup>3</sup>/sec
- Rw water flow, #/sec., ft<sup>3</sup>/sec

### Subscripts

- g actual gas flow in total pipe cross-section, used in Lockhart and Martinelli correlation
- G actual gas flow
- 04 fictitious all-gas flow
- 1 actual liquid flow in total pipe cross-section, used in Lockbart and Martinelli
- L actual liquid flow
- 14 fictitious all-liquid flow
- SP single-phase
- TP two-phase
- tt turbulent-turbulent flow, used in Lockhart and Martinelli correlation

# These data plotted Figure 5.

### SAMPLE CALCULATION

Press Drop Across Orifice (Or Venturi) (8)

$$\sqrt{V_0^2 - V_i^2} = c \sqrt{2g} H_V$$

$$H_V = \frac{V_0^2 - V_i^2}{2g c^2}$$

For 5/32" Venturi, 1.7 GPM Water, & 3/4" Sch. 40 Pipe

$$V_{i} = \frac{1.7 \text{ GPM}}{60 \text{ Sec/min}} = \frac{8.33 \text{ GAL}}{231 \text{ GAL}} = 1.02 \text{ Fr/sec}$$

$$V_{o} = \frac{1.7}{144 \times 4} = \frac{F_{T}^{3}}{60 \times (.1562)^{2} \text{ fr}} = 28.4$$

c = .98 (Assumed Constant For Venturi) varies For Orifice, Depending on  $R_{c_0}$  and Diameter Ratio.

$$H_{y} = \frac{(28.4)^{2} - (1.02)^{2}}{2 \times 32.17 \times (.98)^{2}} = 13.0 \text{ Fr. WATER}$$

$$H_{y} = \frac{13.0 \text{ Fr. H_{20}}}{1.045 \text{ Fr. H_{20}}} = 12.4 \text{ IN. HG}$$

Note:

 $H_{G}$  has effective Sp.G. of 12.6 because water is above mercury in manometer.

(8) Ref. 3

# REDUCTION OF CHENOMETH EQUATION

$$\frac{\Delta P_{G}^{+}}{\Delta P_{L}^{+}} = \frac{\left[\left(\frac{f_{G}^{+}L}{D}\right) + \leq K\right] \left[\frac{W_{L}W_{G}}{A}\right] \left[\frac{1}{2g \mathcal{R}_{G}}\right]}{\left[\left(\frac{f_{L}^{+}L}{D}\right) + \leq K\right] \left[\frac{W_{L}W_{G}}{A}\right] \left[\frac{1}{2g \mathcal{R}_{L}}\right]}$$

Because L . O For Venturi:

$$\frac{\Delta P_{G} +}{\Delta P_{L} +} = \frac{\mathbb{E} K P_{G}}{\mathbb{E} K P_{G}}$$
$$= \frac{P_{L}}{P_{G}}$$

The above expression is tabulated in Column 19 and is obtained by dividing water density  $= 62.3 \,\#/\text{Ft}^3$  by air density Column 7, determined for test conditions.
