## SUMIMARY

The thermodynamio properties of trimetinylanine have been evaluated at temperatures from $32^{\circ} \mathrm{F}$ to $600^{\circ} \mathrm{F}$ and from the saturation pressure to $2000 \mathrm{lb} / \mathrm{in}^{2}$ based on available experimental data. An equation relating the pressure, volume and temperature of the system has been derived for the range in whion experimental data were avallable and it was used to evaluate the thermodynamic properties in this range. Values for pressure, volume, temperature, enthalpy and entropy have been presented in the form of tables and graphs.

## INERODOETION

The increasing use of substituted amines in the chemical and petroleum industries makes desirable a compilation of their thermodynamic properties under various conditions of temperature and pressure. These data are necessary for many engineering calculations such as plate to plate oalculations in distillation or compressor design. While suoh charts have been prepared at low temperatures and pressures for other substituted amines no evaluation of these properties for trimethylamine has been prepared up to tnis time. It is the purpose of this paper to present values of the thermodynamic properties of trimethylamine in the easily used form of tables and graphs.

The requirements for evaluating the network of thermodynamic properties for any compound are not absolutely fixed, but they should include some thermal and some voiumetric data. While it is possible using ceneralizations to deterinine values for thermodynamic properties from direct data for the normal boiling point, specific gravity of the liquid and chemical structure, such values will be inherently less accurate tian those based on more complete direct experimental data. Complete evaluation of the thermo-
dynamic properties from experimental data requires values for entialpies, entropies, latent neats, heat capacities and Joule-Thomson coefficients as well as PVT data in the saturated and superheated vapor regions. Usually such complete data are unavailable and the properties are evaluated by a combination of experimental data and data taken from averaged values for other similar materials. (1)

In the present study available experimental data were gathered and used as a basis for evaluating the properties of trimethylamine. Extrapolation and interpolation were used in extending the available data and in those regions where experimental data were completely lacking, generalized methods of Hougen et al (2) and Hansen (3) were used. The need for additional experimental data is evident.

## SOUROES OF DATA

The iiterature survey undertaken in order to secure date for use in calculating the thermodynanic properties of trimethylamine disclosed a suxprising lack of material on this compound. The exceedingly small amount of PVT data was the greatest cause of difficulty and with the notable exception of the determinations of Day and Felsing $(4,5)$ over a rather limited temperature and pressure range near the critical point, PVI data were nonexistent. In the course of investigation (5) the critical constants were also determined quite acourately. The saturated liquid volume was available from the work of Swift (6) over tife temperature range 0 to 3500 and of Pelsing and Fhillips (7) in the range -20 to $+45^{\circ} \mathrm{C}$. At temperatures from $45^{\circ} \mathrm{C}$ to the oritical point no data were available. The deviation from ideality of trimethylamine at $0^{\circ} \mathrm{C}$ has been calculated by Arthur and Felsing (19) with the aid of an equation which relates the pressure-volune product to the pressure.

Considerable work has been done evaluating the vapor pressure of trimethylamine over a wide temperature range from $-90^{\circ} 0$ to the critical point $(5,8,9,10,11)$. The equations derived by Swift and Eochandel (9) and by Day and Felsing (5) covered the temperature range of the pre-
sent investigation. The molal heat of vaporization has been reported by several investigators (7,8,y). Aston et al (8) have reported values at the normal boiling point and at one other temperature which were checked calorimetrically and appear to be acourate. These inveatigators also determined values of entropy at several temperatures in the ideal gaseous state and there is good agreement with other reported values (12). Kobe and Harrison (12) using data obtained by Aston and others $(8,13)$ evaluated a four-term heat capacity aquation from which they oaloulated entialpy and entropy values for trimethylamine in the ideal gaseous otate. This heat capacity equation was used in the present investigation.

## DERIVATION OF EGUATIONS USED IN CALCULATIUNS

Several hundred equations of state have been proposed to express the PVI relationship of gases but none has been found to be universally satisfactory, and most are applicable only over a limited range of temperatures and pressures. The most generally satisfactory equation of state is that of Beattie and Bridgeman (14) wherein the various constants must be determined uniquely for each gas. tharon and Turnbull (15) using the approximate form of the Beattie-Bridgeman equation, explicit in volume, have derived a series of equations wiich are complete analytical expressions for the calculation of changes in enthalpy and entropy. Initial work was done on this project using their method but comparison of the results obtained with this method, and the available experimental data indicated that it was unsatisfactory, even at low pressures, near the oritical point. Since this project covers the region below $T_{r}=1.2$ a different approach was necessary.

The equation of state may be written

$$
\begin{equation*}
\mathrm{PV}=\mathrm{ZRT} \tag{1}
\end{equation*}
$$

where $Z$ is termed the compressibility factor and is a function of pressure, temperature and the nature of the
gas. Values of $z$ at any temperature and pressure can be calculated from compressiblily data since

$$
\begin{equation*}
\mathrm{Z}=\frac{\mathrm{PV}}{\mathrm{R}^{\prime}} \tag{2}
\end{equation*}
$$

When values of the compressibility factor of a gas are known, all calculations involving its PVT relationskips may be carried out by simple proportionalities derived from Equation (1).

Experimental compressibility data for trimethylanine were available at the following temperatures and pressures $(4,5)$.

| $t\left(O_{C}\right)$ | $P(2 t m)$ |
| :--- | :--- |
| 175 | $47-49$ |
| 200 | $58-64$ |
| 225 | $69-79$ |
| 250 | $80-94$ |
| 275 | $90-106$ |

Using these experimental data, the constants for an eapirical equation for $Z$ were evaluated. The equation takes the form of a power series in the pressure; thus,

$$
\begin{equation*}
Z=1+B P+C P^{2}+D P^{3} \tag{3}
\end{equation*}
$$

$B, C$ and $D$ are virial coefficients which depend on the temperature only. The simplest funotions relating the virials to $T$ were sougnt and it was found that the following equations gave the most satisfactory agreement:

$$
\begin{align*}
& B=b_{1} T^{-1}+b_{2} T^{-2}+b_{4} T^{-4}  \tag{4}\\
& C=o_{1} T^{-2}+o_{2} T^{-3}+c_{3} T^{-5}  \tag{5}\\
& D=d_{1} T^{-3}+d_{2} T^{-4}+d_{3} T^{-6} \tag{6}
\end{align*}
$$

The equation thas involves nine empirical constants derived from the experimental data and has the form:
$z=1+\left(\frac{b_{1}}{T}+\frac{b_{2}}{T^{2}}+\frac{b_{4}}{T^{4}}\right) P+\left(\frac{o_{1}}{T^{2}}+\frac{o_{2}}{T^{3}}+\frac{c_{3}}{T^{5}}\right) P^{2}+\left(\frac{d_{1}}{T^{3}}+\frac{d_{2}}{T^{4}}+\frac{d_{3}}{T^{6}}\right) P^{3}$

While this equation is valid over a temperature range from $T_{r}=1.1$ to $T_{r}=1.28$, in the range $T_{r}=1.05$ to $T_{r}=1.1$ it was necessary to include a tenth term to reproduce the experimental values. The B virial in Equation (3) then takes the form:

$$
B=b_{1} 1 T-1+b_{2} \quad T-2+b_{3} \quad T-3+b_{4} \quad T-4
$$

The constants for Equation (7) were evaluated using the Hollowing metinod:

1. Values of the compressibility factors were calculated using Equation (2) and experimental volume data and were plotted as a function of temperature and pressure. Since data at five temperatures were available five curves were obtained.
2. Solution of three simultaneous equations of the form:

$$
Z=1+B P+C P^{2}+D P^{3}
$$

using three selected compressibility factors and corresponding pressures from each curve gave values of $B, C$ and $D$ which enabled values on these curves to be
reproduced with reasonable accuracy.
3. The five values of each of the constants $B, C$ and $D$ were then plotted against the reciprocal of the temperature at which they were evaluated. Figure (1) is such a curve for values of 0 . Evaluation of Equations ( 4,5 and 6) to reproduce the resulting curves gave the values which appear in Table I.

In as much as the thermodynamic properties of a materdial can be calculated from derived relationships, the empirincally determined equation for the compressibility factor was used to evaluate the effect of pressure on the enthalpy and entropy of trimethylamine. It has been shown (16,17) that the enthalpy of an ideal gas is independent of pressure and a function only of temperature. However, at elevated pressores all actual gases deviate from ideal behavior, and enthalpy changes with change in pressure particularly in the critical region. The enthalpy of a real gas relative to the enthalpy of an ideal gas when both are at the same temperature may be obtained by integration of

$$
\begin{equation*}
\left(\frac{\partial H}{\partial P}\right)_{T}=V-T\left(\frac{\partial V}{\partial T}\right)_{P} \tag{8}
\end{equation*}
$$

between the limits of existing pressure and zero pressure where all gases behave ideally and the enthalpy becomes independent of pressure. Thus

$$
\begin{equation*}
\left(H^{*}-H\right)_{T}=\int_{0}^{P}\left[T\left(\frac{\partial V}{\partial T}\right)_{P}-V\right]_{T} \partial P \tag{9}
\end{equation*}
$$

The value of (ns-H) T may be expressed in terms of the compressibility factor as a variable and thus obtained from these factors for a specific material. Differentiation of Equation (1) gives

$$
\begin{equation*}
\left(\frac{\partial V}{d T}\right)_{p}=\frac{R}{P}\left[Z+T\left(\frac{d Z}{d T}\right)_{p}\right] \tag{10}
\end{equation*}
$$

combining Equations (8) and (10),

$$
\begin{equation*}
\left(\frac{\partial H}{\partial P}\right)_{T}=-\frac{R T^{2}}{P}\left(\frac{\partial Z}{\partial T}\right)_{P} \tag{11}
\end{equation*}
$$

$$
\begin{aligned}
& \text { On substituting Equation (7) } \\
& \left(\frac{\partial H}{d P}\right)_{T}=-\frac{R T^{2}}{P}\left(\frac{\partial}{\partial T}\left[1+\left(\frac{b_{1}}{T}+\frac{b_{2}}{T^{2}}+\frac{b_{4}}{T^{4}}\right) P+\left(\frac{c_{1}}{T^{2}}+\frac{C_{2}}{T^{3}}+\frac{c_{3}}{T^{5}}\right) P^{2}+\left(\frac{d_{1}}{T^{3}}+\frac{d_{2}}{T 4}+\frac{d_{3}}{T^{6}}\right) P P_{p}^{3}\right)_{p}(12)\right.
\end{aligned}
$$

Differentiating and combining terms

$$
\begin{equation*}
\left(\frac{d A}{d p}\right)_{T}=A\left[\left(d_{1}+\frac{2 b_{2}}{T}+\frac{4 l_{4}}{T^{3}}\right)+\left(\frac{2 c_{1}}{T}+\frac{3 C_{2}}{T^{2}}+\frac{5 C_{3}}{T^{4}}\right) P+\left(\frac{3 d_{1}}{T}+\frac{4 d_{2}}{T^{3}}+\frac{6 d_{3}}{T^{5}}\right) P^{2}\right] \tag{13}
\end{equation*}
$$

Integration between $p=0$ and $p$ gives the desired expression
$H^{*}-H_{p}=R\left[\left(l_{1}+\frac{2 l_{2}}{T}+\frac{4 l_{4}}{T^{3}}\right) P+\left(\frac{2 C_{1}}{T}+\frac{3 C_{2}}{T^{2}}+\frac{5 C_{3}}{T^{4}}\right) \frac{P^{2}}{2}+\left(\frac{3 d_{1}}{T^{2}}+\frac{4 d_{2}}{T^{3}}+\frac{6 d_{3}}{T^{5}}\right) \frac{P^{3}}{3}\right]$.
The entropy deviation of a gas from ideal behavior may be derived in a similar fashion from the Maxwell relation

$$
\begin{equation*}
\left[d S=-\left(\frac{d U}{d T}\right)_{p} d p\right]_{T} \tag{15}
\end{equation*}
$$

From Hougen and Watson (17) pg. 4y7, Equation 24,

$$
\left(S_{p}^{*}-S_{p}\right)_{T}=-R \int_{0}^{P}\left[\frac{1-Z}{P}-\frac{T}{P}\left(\frac{d Z}{d T}\right)_{p}\right] d p
$$

Substitution of Equation (7), differentiation and combinaction of terms gives:

$$
\begin{equation*}
\left(S_{P}^{*}-S_{P}\right)_{T}=-R \int_{0}^{P}\left[\left(\frac{h_{2}}{T^{2}}+\frac{3 h_{4}}{T^{4}}\right)+\left(\frac{C_{1}}{T^{2}}+\frac{2 C_{2}}{T^{3}}+\frac{4 C_{3}}{T^{5}}\right) P+\left(\frac{2 d_{1}}{T^{3}}+\frac{3 d_{2}}{T^{4}}+\frac{5 d_{3}}{T^{6}}\right) P^{2}\right] d P \tag{17}
\end{equation*}
$$

Integration between $p=0$ and $p$ gives the desired expression;

$$
\begin{equation*}
\left.\left(S_{p}^{*}-S_{p}\right)_{t}=-R\left[\frac{L_{2}}{T_{2}}+\frac{3 L_{4}}{T^{4}}\right) P+\left(\frac{c_{i}}{T^{2}}+\frac{2 C_{2}}{T^{3}}+\frac{4 C_{3}}{T^{5}}\right) \frac{P^{2}}{2}+\left(\frac{2 d_{1}}{T^{3}}+\frac{3 d_{2}}{T^{4}}+\frac{5 d_{3}}{T^{6}}\right) \frac{P^{3}}{3}\right] \tag{18}
\end{equation*}
$$

## MEIHOD OF CALCULATION

In the superheated vapor region between temperatures of $400^{\circ} \mathrm{F}$ and $540^{\circ} \mathrm{F}$ and pressures of $700 \mathrm{lb} / \mathrm{in}^{2}$ to 1200 1b/in ${ }^{2}$ calculations for specitic volume, enthalpy and entropy are based on the equations derived from available experimental data. In the saturated vapor and liquid region and in the superheated vapor region outside the limits of pressure and temperature given above, oalculations are made using the method of Hougen, Lydersen and Greenkorn (2). This method is based on the theorem of corresponding states and the values for PVT relationships as well as for each thermodynamic property have been obtained by these authors by evaluating 82 different compounds for which PVI data and the three critioal constants $\mathrm{Pc}, \mathrm{Tc}$ and Vc were available. All constants and equations used in this present study in making these calculations are listed in Table II.

The following steps were traversed in appraising the thermodynamic properties:

1. An arbitrary datum of unit mass of the saturated liquid at $32^{\circ} F$ was chosen for zero value of enthalpy and a datum of 00 H for a zero value of entropy. The value for entropy at $32^{\circ} \mathrm{F}$ in the
ideal gaseous stete at one atmosphere is 1.13534 Btu/1b ${ }^{\circ} \mathrm{R}$ (12).
2. The latent heat reported by Aston et al (8) as $166.95 \mathrm{Btu} / 1 \mathrm{~b}$ was used in preference to other reported values. Values of the latent heat of vaporization from $32^{\circ} \mathrm{F}$ to the critical temperature were oomputed from Aston's value using Watson's method (18).
3. The following vapor pressure equations were used:
a) from 320 F to 1200 F (9)
$\log 10 P($ man $)=-(2018.37 / T)-6.0303 \operatorname{LOE} T+24.91300$
b) from $120^{\circ} \mathrm{F}$ to $270^{\circ} \mathrm{F}$ (5)
$\log _{10} P(\mathrm{~mm})=-1202.2908 / T+7.250828$
c) from $270^{\circ} \mathrm{F}$ to critical temperature (5) $\log _{10} \mathrm{P}(\mathrm{mm})=-738.6065 / T+.0028426 T 4.914884$
4. Volume of the saturated liquid was calculated from $32^{\circ} \mathrm{F}$ to $120^{\circ} \mathrm{F}$ using (7)
density $(\mathrm{g} / \mathrm{co})=0.87406-4.433 \times 10^{-4} \mathrm{~T}-1.29236$ $\times 10^{-6} \mathrm{~T}^{2}$. From 1200 F to critical temperature Hanson's method (3) was used. This method is based on the theorem of corresponding states and it allows calculation of the volume of a liquid at temperatures from the normal boiline point to the oritical temperature. The only required data are the critical temperature and the oritical volume, which are available for trimethylamine.
5. Volume of tice saturated vapor was calculated using the compressibility ractors taxen fron ref (2) using a value of $2 c=.286$ and Equation (1).
6. Enthalpy of the vapor at zero pressure and $32^{\circ} \mathrm{F}$ was obtained by adding the isotnermal variation of entnalpy with pressure for saturated vapor to the latent heat of vaporization at tals temperature. Values of the enthalpy over tie entire temperature range at zero pressure were obtained by inteerating the neat capacity Echation (12) at constant pressure with respect to the temperature in O between $32^{\circ} \mathrm{F}$ and the temperature in question.
7. Values of entralpy of the vapor at different pressures were obtained by subtracting the isothernal variation in enthalpy from the enthalpy at zero pressure. In the range $400^{\circ} \mathrm{F}$ to $540^{\circ} \mathrm{F}$ and $700 \mathrm{Ib} / \mathrm{in}^{2}$ to $1200 \mathrm{Ib} / \mathrm{in}^{2}$ the isothermal osange in ent alpy with change of pressure was calculated from Equation (14). At other temperatures and pressures in the superheated vapor region and in the saturated vapor region the isotnernal change in enthalpy with oharge of pressure was obtained from ref. (2).

8, Values of the entialpy of the saturated licquid were found by subtracting the enthalpy of vaporization from tae enthalpy of the saturated vapor at the saine temperature.
9. Values of the Entropy over the entire temperature range in the ideal state at one atnosphere were found by evaluating the expression

$$
\Delta S=\int_{T_{1}}^{T_{2}} C p \frac{d T}{T}
$$

between 320 and the temperature in question and adding this value to the entropy in the 1deal gaseous state at one atmospinere at $32^{\circ} \mathrm{F}$.
10. Values of entropy of the vapor at different pressures were obtained by subtracting the isothermal variation in entropy from the entropy at one atmosphere. This variation is a conbination of two correction factors, one for change in pressure under ideal beravior and a second for deviation from ideal behavior at the given temperature and pressure. The isotheraal change in entropy with change in pressure for ideal behavior is evaluated from the expression

$$
-R \ln \frac{P_{2}}{P_{1}}
$$

In the range $400^{\circ} \mathrm{F}$ to $540^{\circ} \mathrm{F}$ and $600 \mathrm{lb} / \mathrm{in}^{2}$ to $12001 \mathrm{~b} / \mathrm{In}^{2}$ the isothermal correotion for devia. tion fron ideal behavior was obtained from Equation (18). At other temperatures and pressures in the superheated vapor region and in the saturated vapor region the isothermal correction for deviation from ideal behavior was obtained from ref. (2).
11. Values of the entropy of vaporization were derived by dividing the latent heat of vaporization by the absolute temperature.
12. Values of the entropy of the saturated liquid were found by subtracting the entropy of vaporization from the entropy of the saturated vapor at the same temperature.
13. Values of the volume in the superhsated vapor reeion were computed from Equation (1) and compressibility factors derived from Equation (7) where applicable, and from ref. (2) at other temperatures and pressures.

## DISCUSSION OF KESULTS

The lack of available experimental data in the literature makes it difficult to estimate the accuracy of this work. Since certain portions of the work are based on averaged data rather than direct experifental data, a hign order of accuracy could not be attained. However, generalized methods for estinating thermodynamic properties of pure fluids based upon the theorem of corresponding states are commonly used where reliable experimental data or accurate equations of state for specific fluids are not available. These methods are satisfactory for most engineering purposes, such as process design, where extreme accuracy is not required. The data of Hougen et al (2) whink were used in this inveatigation are a decided advance over previous generalized methods in that a third parameter, the critical compressibility factor $Z_{c}$, has been used to increase the acouracy. Methods have been developed which allow cextain portions of the calculated data to be checked and this has been done.

Saturated liquid volumes in the range $32^{\circ} \mathrm{F}$ to $100^{\circ} \mathrm{F}$ were checked using the equation derived by Swift (6) from experimental data, and give good agreement with those re-
ported in this work. The acouracy of the liquid volume above this temperature range is that of Hansen's method (3) which has been reported as $\pm 8 \%$. The equation developed by hageenmacher (20) was used to evaluate the volume of the saturated vapor at selected points and these values were compared witn the values calculated using the compressibility factor and Equation (1). This equation is $\nabla_{g}+\nabla_{1}=(C T / P)-2 B$ where $O=R / m o l$. wt. and $B=$ ( $\left.O T_{c} / 2 P_{C}\right)-V_{C}$. There is no significant deviation between the values obtained by these two methods. Values of the volume in the superheated vapor region where Equation (4) is applicable are consistent with the experimental data. At other temperatures and pressures the accuracy is dependent on the accuracy of the compressibility factor taken from reference (2). The deviation of these values from tne experimental data from which they were derived is reported as inoreasine from zero at low pressures up to $2.5 \%$ in the oritical region and tien diminishing to $2.0 \%$ at higner pressures. The same order of accuracy should hold in tnis work.

Aston et al (8) have given values for the latent heat of vaporization at two temperatures and therefore Watson's inethod of obtaining the latent heat of vaporization at other temperatures could be checked. Agreement was obtained within $1 \%$ and values of the latent heat at
other temperatures s:ould be of the same order of accuracy.

Enthalpy values in the saturated and superiested vapor regions were obtained by correcting the entialpy of the ideal eas as previously described. The entialpy of the ideal gas at the datun temperature of $32^{\circ} \mathrm{F}$ was egtablislied by adding a correotion for non-ideailty of 4 Btu / 16 to the enthalpy of the saturated vapor at that teaperature. If this correction is in error by $30 \%$ the value for the enthalpy at the datum plane has an error of 0.5 . Such an error is well within the acouraoy of this work. The use of the derived equation for (theH) in one region and values of (t:H-h) from reference (2) in other regions resulted in some inoonsistencias in values of entialpy in the superheated vapor region. In this region values of enthalpy were plotted on a large scale eraph and smoothed values, to remove the inconsistencies, tainen from this fraph are given in the tables. Figure 2, is such a graph for values at $700 \mathrm{lb} / \mathrm{In}^{2}$ abs. Although fougen et al (2) bave not indicated the order of accuracy obtained using $t_{i}$ eir data, pougen and watson (17) estimate the magnitude of the maximum error in tie correction for non-ideality which nay be encountered usine generalized metrods as 30\%. Since the generalized metiod used in this work is more accurate tian those for which this estimation was made and the
correction terins are relatively small in thenselves, the values given in this work should be more accurate tnan tais.

Values of tie entropy in the ideal gaseous gtate at one atmosphere were obtained using the data given by Kobe and harrison (12) who report an average error of $0.18 \%$.

The accuracy of entropy values at other pressures in the real gas state are dependent upon the acouracy of the corrections used. Hougen and Watson (17) estimate the maximum errors in generalized noneideality corrections for the entropy of gas as 30\%. The accuracy of the corrections used here should be better than this for the same reasons as given above. Again the use of two metnods for obtaining these corrections, derived equation and reference (2), resulted in some inconsistencies and smoothed values are given in the tables.

The present work is the only systematio compilation of thermodynamic properties of trimethylamine. It is recomwended that these values be used in engineering calculations where extreme acouracy is not required. Further experimental data must be collected before a more accurate evaluation of these propertier may be presented.

## APPENDIX

NOMENCLAIURE

| P | pressure |
| :---: | :---: |
| V | volume |
| 2 | compressibility factor |
| R | gas constant |
| T | absolute temperature |
| $t$ | temperature of or ${ }^{\circ} \mathrm{C}$ as noted |
| B, C, D | viral coefficients |
| $b_{1}^{\prime}, b_{2}^{\prime}, b_{3}^{\prime}$, | $\begin{aligned} & b_{4}^{\prime}, c_{1}, c_{2}, c_{3}, d_{1}, d_{2}, d_{3}, b_{1}, b_{2}, b_{4}-\text { con- } \\ & \text { stants in the equation for } z^{2} \end{aligned}$ |
| $\mathrm{C}_{\mathrm{p}}$ | speoific heat at constant pressure |
| H | enthalpy |
| S | entropy |
| $\lambda$ | heat of vaporization |
| * | ideal gaseous state when used as superscript |
| p | constant pressure when used as subscript |
| T | constant temperature when used as subscript |
| $\boldsymbol{r}$ | reduced condition when used as subscript |
| 0 | critical state when used as subscript |
