## ABSTRACT

The natural frequencies of the transverse vibration of a thin, isotropic, circular plate with free, clamped, and simply supported edge conditions were studied extensively. The frequency equation for each edge condition was derived from the classical partial differential equation of plate vibration. These equations, which are in terms of Bessel functions, were then solved numerically to find the natural frequencies. Since the accuracy of the Bessel function values is very important in evaluating these frequencies, a comprehensive digital computer program was devised to calculate these values to eleven digit accuracy. In this Bessel function program four different methods were required to insure a rapid convergence. They are: (a) Infinite Series; (b) Asymptotic Series; (c) Recursion Formula; (d) Approximate Numerical Method.

The nodal patterns are known from the form of the solution to the fourth order partial differential equation of the vibrating plate. The order of the Bessel functions in the frequency equation corresponds to the number of equally spaced nodal diametral lines. The eigenvalues of this equation determine the number of concentric nodal circles
which are present in the various nodal patterns. For each edge condition, twenty-six frequencies were computed for each of the first twenty-six orders of the frequency equation. The accuracy of these computations has been carried out to ten significant figures. Methods to be used in computing the radii of the nodal circles corresponding to these frequencies were also discussed. However, these values were not obtained.

## ACKNOWLEDGMENTS

The author wishes to express his appreciation to his adviser Doctor Benedict Sun for his consultation through out the extent of this thesis. He also wishes to thank the members of his committee, Doctor Arnold Allentuch and Professor Aaron Deutschman, for their recommendations. The author also wishes to acknowledge the assistance given by the staff of the Computer Services Department of Newark College of Engineering in their operation of the RCASpectra $70 / 45$ computer.

## INTRODUCTION

The analytical solution of the vibration of a solid elastic plate was not developed until the early part of the nineteenth century. Experimental work had been carried on during previous years by the German acoustician E.F.F. Chladni. He produced figures of the nodal pattern shapes by sprinkilng sand on vibrating plates. The Emperor Napoleon of France provided a prize of 3000 francs to be awarded by the Institute of France for satisfactory completion of the mathematical theory of the vibrations of plates. This prize was awarded in 1815 to Mlle. Sophie Germain. She presented the correct fourth order differential equation, but her choice of boundary conditions proved to be incorrect. ${ }^{1}$ Most of the difficulty in obtaining the correct boundary conditions arose when the free edge was considered. Poisson gave three equations which were to be satisfied at all points of a free edge. Kirchhoff later proved that in general it would be impossible to satisfy all three of Poisson's equations. However, he also noted that
${ }^{1}$ J.W.S. Rayleigh, The Theory of Sound (New York, 1945), Vol. I, p. XVI.
one of Poisson's equations is true identically for the symmetrical vibrations of a circular plate. Thus, Poisson's theory was correct even though he used three boundary conditions instead of two. In 1850, Kirchhoff resumed his work and completed the theory of the vibration of circular plates. ${ }^{2}$

Kirchhoff calculated the first few solutions of the equation for the natural frequencies of a free plate. This equation was found by substituting the solution of the fourth order differential equation of motion into the two boundary conditions and equating the results. After the first few values, the roots of the frequency equation were extremely difficult to find. The smaller roots were obtained by a trial and error method using interpolated values of Bessel functions taken from available tables. This type of solution is very time consuming, and the hand calculations were of limited accuracy. For the larger roots, asymptotic or semiconvergent descending series were used for the Bessel functions, and the frequency equation was written in the form of a series. This method,first used
${ }^{2}$ Ibid., pp. 369-370.
by Kirchhoff himself, was later used by Lord Rayleigh and Airey. Rayleigh gives an extensive study of vibrating plates with free and clamped edges. He also presents some of Kirchhoff's original work and gives his own results to Kirchhoff's equations. ${ }^{3}$ Airey used a different semiconvergent series and presented the first ten roots for each of the first four orders of the frequency equation for clamped and free plates. 4

With advances in mathematics, new semiconvergent series were developed to produce larger values with greater accuracy. H. Carrington, in 1925, utilized more extensive Bessel function tables to find all the roots less than sixteen with five digit accuracy. He then proceeded to develop the frequency equation in terms of an asymptotic or semiconvergent series, but he did not give any further results. 5

Some of the more recent works have dealt with elastic end restraints. Since the two extreme values of this type

${ }^{5}$ H. Carrington, "The Frequencies of Vibration of Flat, Circular Plates, Fixed at the Circumference," Philosophical Magazine, Series 6, Vol. 50 (1925), pp. 1261-1264.
of analysis are the clamped and simply supported edges, some results could be used for the natural frequencies of the simply supported case. C. Lakshmi Kantham gives the first root for each of the first four orders. ${ }^{6}$ N. Gajendar solved the problem of a vibrating plate with inftial displacement and velocity. He gives very little numerical results. ${ }^{7}$ R.Y. Bodine has calculated the natural frequencies of a plate which is simply supported along a circle of arbitrary radius. He gives results for supports varying from the center of the plate to the edge of the plate. His results include the first four orders with arguments up to eighteen. 8

Thus far the range of orders and arguments for which the frequency equation could be solved has been limited by the difficulty in evaluating the Bessel functions.

R.Y. Bodine, "Vibrations of a Clrcular Plate Supported by a Concentric Ring of Arbitrary Radius," The Journal of the Acoustical Society of America, Vol. 41 (June, 1967), p. 1551.

For the first few orders, the infinite series could be used for small arguments, and the asymptotic or semiconvergent series could be used for the larger arguments. The values which could be obtained by these methods have been tabulated in various Bessel functions handbooks. To find Bessel functions of higher orders, the recursion formulas may be used if the argument is greater than the order. If the argument is less than the order, the number of significant digits decreases rapidly with each recursion. For this reason most Bessel function tables do not contain values for small arguments of large orders. The development of the high speed digital computer allowed a entirely new approach to the problem. A numerical technique was given by F.W.J. Olver, who utilized a reverse recursion process to find the Bessel functions of arguments which are less than the order. ${ }^{9}$

Chapter II contains a complete development of the equations for the natural frequencies of a vibrating circular plate with its edge either clamped, simply supported
$9_{\text {Milton }}$ Abramowitz and Irene Stegun, Handbook of Mathematical Functions, (Washington, 1968), pp. 355-433.
or free. It also contains the derivation of the equations to find the radii of the nodal circles, and a method of obtaining these radil from ratios of the natural frequencies. Chapter III contains a study of the various methods of computing Bessel functions of the first kind, and Modified Bessel functions of the first kind. An analysis was made of the range of orders and arguments for which each method is accurate. This information was then used in devising a computer program to evaluate these Bessel functions for orders from zero to thirty-three, and for any argument whose Bessel function does not exceed the capacity of the computer being employed. An analysis of the entire computer program used to find the natural frequencies is given in Chapter IV. The accuracy of this program is carried out to ten significant figures.

## FREQUENCY AND NODAL PATTERN EQUATIONS

General Displacement Relationships
The differential equation of motion of a thin, flat, circular plate with no external load, which is homogeneous and isotropic, and which experiences small displacements in the vertical direction is ${ }^{2}$

$$
\begin{equation*}
\frac{E I g}{\left(I-v^{2}\right) \gamma H} \nabla^{4} W=-\frac{\partial^{2} W}{\partial t^{2}} \tag{1}
\end{equation*}
$$

where

$$
\nabla^{4}=\nabla^{2} \nabla^{2}=\left[\frac{\partial^{2}}{\partial r^{2}}+\frac{1}{r} \frac{\partial^{2}}{\partial r^{2} \partial \theta}+\frac{1}{r^{2}} \frac{\partial^{2}}{\partial \theta^{2}}\right]^{2}
$$

and
$I=$ moment of inertia of a unit width of
$H=$ cross section
$H=$ plate thickness
$E=$ Young's Modulus of Elasticity
$V=$ specific weight of the material
$X=$ acceleration due to gravity
$X=$ time
$I_{\text {E. Volterra and E.C. Zachmanoglou, Dynamics of }}$ Vibrations (Columbus, 1965), p. 379.
8.

$$
\begin{aligned}
\mathrm{W}= & \text { displacement of the middle surface of } \\
& \text { the plate in the vertical direction } \\
\mathrm{r} \text { and } \theta= & \text { polar coordinates whose origin is at } \\
& \text { the center of the plate }
\end{aligned}
$$

Any consistent set of units may be used.

Equation (1) can be reduced to three total differential equations by using the method of separation of variables. The displacement can be written as,

$$
\begin{equation*}
W(r, \theta, t)=R(r) \theta(\theta) T(t) \tag{2}
\end{equation*}
$$

If the proper substitutions are made into the evolving equations, the final result is the following set of total differential equations.

$$
\begin{align*}
& \frac{d^{2} T(t)}{d t^{2}}+\hat{\omega}^{2} T(t)=0  \tag{3}\\
& \frac{d^{2} \theta(\theta)}{d \theta^{2}}+k^{2} \theta(\theta)=0  \tag{4}\\
& \frac{d^{2} R(r)}{d r^{2}}+\frac{1}{r} \frac{d R(r)}{d r}+\left[ \pm \lambda^{2}-\frac{k^{2}}{r^{2}}\right] R(r)=0 \tag{5}
\end{align*}
$$

Where

$$
\begin{align*}
\hat{\omega} & =\text { natural frequency } \\
k & =\text { a constant } \\
\lambda^{2} & =\frac{\hat{\omega}}{\hat{\beta}}  \tag{6}\\
\beta^{2} & =\frac{D g}{\gamma H} \tag{7}
\end{align*}
$$

$D=\frac{E I}{\left(1-v^{2}\right)}$
Which is called the flexural rigidity of the plate.

The general solutions of Eq. (3) and Eq. (4) are respectively,

$$
\begin{align*}
& T(t)=A \cos (\hat{\omega} t)+B \sin (\hat{\omega} t)  \tag{9}\\
& \theta(\theta)=C \cos (k \theta)+D \sin (k \theta) \tag{10}
\end{align*}
$$

where $A, B, C$, and $D$ are constants depending on the initial values and the boundary conditions of the particular plate. In order for the displacements to be continuous, $\theta(e)$ must be periodic with a period of $2 \pi$. Therefore, $k$ must be a integer.
$\mathrm{k}=\mathrm{n}=1,2,3, \ldots$
If a change of variables is made in Eq. (5) with $\rho=\lambda r$ in conjunction with the positive sign, and $\rho=1 \lambda r$ in conjunction with the negative sign, the resulting equation is

$$
\begin{equation*}
\frac{d^{2} R(\rho)}{d \rho^{2}}+\frac{1}{\rho} \frac{d R(\rho)}{d \rho}+\left[1-\frac{n^{2}}{\rho^{2}}\right] R(\rho)=0 \tag{12}
\end{equation*}
$$

Equation (12) is of the form of Bessel's Differential Equation, and its solution is of the standard form associated with equations of this type. The general solution is, after replacing $\rho$ by $r$.

$$
\begin{equation*}
R(r)=A_{n} J_{n}(\lambda r)+B_{n} J_{n}(i \lambda r)+E_{n} Y_{n}(\lambda r)+F_{n} Y_{n}(i \lambda r) \tag{13}
\end{equation*}
$$

where

$$
\begin{aligned}
& J_{n}(x)=\text { Bessel function of the first kind } \\
& Y_{n}(x)=\text { Bessel function of the second kind } \\
& n \\
& \\
& A, B, E, F=\text { the order of the Bessel function } \\
&
\end{aligned}
$$

Bessel functions of the second kind become infinite for zero arguments. Thus, if a plate does not have a hole at its center, the constants $E_{n}$ and $F_{n}$ must be equal to zero since the displacement at the center of the plate must be a finite value.

The time independent solution of Eq. (I), that is, displacement as a function of position alone is

$$
\begin{array}{r}
W(r, \theta)=\left[A_{n} J_{n}(\lambda r)+B_{n} J_{n}(i \lambda r)\right]\left[\begin{array}{c}
\left.c_{n} \cos (n \theta)+D_{n} \sin (n \theta)\right] \\
(n=0,1,2, \ldots)
\end{array}, \begin{array}{c}
n=1
\end{array}\right] \\
(n) \tag{14}
\end{array}
$$

The constants $A_{n}, B_{n}, C_{n}$, and $D_{n}$ must be evaluated from the boundary conditions of the plate.

## Frequency Equations

Clamped Edge. The boundary conditions for a circular plate of radius $a$, which is fixed at the circumference are:
(a) The deflection at the edge is zero.

$$
\begin{equation*}
W(a, \theta)=0 \tag{15}
\end{equation*}
$$

(b) The slope at the edge is zero. ${ }^{2}$

$$
\begin{equation*}
\frac{\partial W(a, \theta)}{\partial r}=0 \tag{16}
\end{equation*}
$$

The substitution of Eq. (14) into Eq. (15) yields,

$$
\begin{equation*}
\left[A_{n} J_{n}(\lambda a)+B_{n} J_{n}(i \lambda a)\right]\left[C_{n} \cos (n \theta)+D_{n} \sin (n \theta)\right]=0 \tag{17}
\end{equation*}
$$

The second term cannot be equal to zero for all values of $\theta$ unless $C_{n}$ and $D_{n}$ are identically equal to zero. This would result in a trivial solution with no motion. Thus, the second term can be eliminated, and the resulting equation is

$$
\begin{equation*}
A_{n} J_{n}(\lambda a)+B_{n} J_{n}(i \lambda a)=0 \tag{18}
\end{equation*}
$$

The substitution of Eq. (14) into Eq. (16) yields by similiar reasoning,

$$
\begin{equation*}
A_{n} J_{n}^{\prime}(\lambda a)+i B_{n} J_{n}^{\prime}(i \lambda a)=0 \tag{19}
\end{equation*}
$$

where the primes denote differentiation with respect to $r$.

The Bessel functions with complex arguments can be replaced by Modified Bessel functions according to the following relationships. 3
2. Timoshenko and S. Woinowsky-Krieger, Theory of Plates and Shells (New York, 1959), pp. 283-284.

George Arfken, Mathematical Methods for Physicists (New York, 1966), p. 397.

$$
\begin{align*}
& J_{n}(i x)=i^{n} I_{n}(x)  \tag{20}\\
& i J_{n}^{\prime}(i x)=i^{n} I_{n}^{\prime}(x) \tag{21}
\end{align*}
$$

The above relationships are substituted into Eq. (18) and Eq. (19) to give,

$$
\begin{align*}
& A_{n} J_{n}(\lambda a)+i{ }^{n} B_{n} I_{n}(\lambda a)=0  \tag{22}\\
& A_{n} J_{n}^{\prime}(\lambda a)+i B_{n} I_{n}^{\prime}(\lambda a)=0 \tag{23}
\end{align*}
$$

Both of these equations can be solved for the ratio $\left(B_{n} / A_{n}\right)$, and set equal to each other,

$$
\begin{equation*}
\frac{B_{n}}{A_{n}}=\frac{-i^{-n} J_{n}(\lambda a)}{I_{n}(\lambda a)}=\frac{-i^{-n} J_{n}^{\prime}(\lambda a)}{I_{n}^{\prime}(\lambda a)} \tag{24}
\end{equation*}
$$

or after cross multiplication,

$$
\begin{equation*}
J_{n}(\lambda a) I_{n}^{\prime}(\lambda a)-I_{n}(\lambda a) J_{n}^{\prime}(\lambda a)=0 \tag{25}
\end{equation*}
$$

The derivatives can be eliminated by the following relationships ${ }^{4}$

$$
\begin{align*}
& J_{n}^{\prime}(x)=\frac{n}{x} J_{n}(x)-J_{n+1}(x)  \tag{26}\\
& I_{n}^{\prime}(x)=\frac{n I_{n}}{x}(x)+I_{n+I}(x) \tag{27}
\end{align*}
$$

The resulting equation is the frequency equation for a clamped plate

$$
\begin{equation*}
J_{n}(\lambda a) I_{n+1}(\lambda a)+I_{n}(\lambda a) J_{n+1}(\lambda a)=0 \tag{28}
\end{equation*}
$$

4 Ibid., pp. 374, 397.

This equation will have an infinite number of solutions, each of the form $\lambda_{n m}$, if the radius is chosen to be unity. The subscript $n$ is the order of the equation, which corresponds to the number of evenly spaced diametral node lines on the plate. The subscript $m$ is the numerical rank of the root, which corresponds to the number of concentric nodal circles. For example, the second root of the second order equation will yield a nodal pattern of two nodal diametral lines and two nodal circles. In this case one of the nodal circles occurs at the fixed edge. The natural frequencies of a specific plate with known physical properties can be found by substituting the solution of Eq. (28) into Eq. (6), Eq. (7) and Eq. (8), that is, Eq. (6) may be written as

$$
\begin{equation*}
\hat{\omega}=\lambda^{2} \sqrt{\frac{D g}{\gamma H}} \tag{6}
\end{equation*}
$$

Simply Supported Edge. The boundary conditions for a circular plate of radius a with a simply supported edge are: 5
(a) The deflection at the edge is zero.

$$
\begin{equation*}
W(a, \theta)=0 \tag{29}
\end{equation*}
$$

5Timoshenko, p. 284.
(b) The bending moment at the edge is zero.

$$
\begin{equation*}
M_{r}(a, \theta)=0 \tag{30}
\end{equation*}
$$

where

$$
\begin{equation*}
M_{r}=-D\left[\frac{\partial^{2} W}{\partial r^{2}}+V\left(\frac{\partial}{r} \frac{\partial W}{\partial r}+\frac{1}{r^{2}} \frac{\partial^{2} W}{\partial \theta^{2}}\right)\right] \tag{31}
\end{equation*}
$$

The first boundary condition has already been evaluated in the previous section. The result was

$$
\begin{equation*}
\frac{B_{n}}{A_{n}}=\frac{-i^{-n} J_{n}(\lambda a)}{I_{n}(\lambda a)} \tag{32}
\end{equation*}
$$

The substitution of Eq. (14) into the second boundary condition for a simply supported plate yields after considerable factoring,

$$
\begin{gather*}
\frac{I}{v}\left[\lambda^{2} J_{n}^{\prime \prime}(\lambda a)-\frac{\lambda^{2} B_{n}}{A_{n}} J_{n}^{\prime \prime}(i \lambda a)\right]+\frac{I}{a}\left[\lambda J_{n}^{\prime}(\lambda a)_{+}+\frac{i B_{n}}{A_{n}} J_{n}^{\prime}(i \lambda a)\right] \\
-\frac{n^{2}}{a^{2}}\left[J_{n}(\lambda a)+\frac{B_{n}}{A_{n}} J_{n}(i \lambda a)\right]=0 \tag{33}
\end{gather*}
$$

By using the following recursive relationships ${ }^{6}$

$$
\begin{align*}
& \frac{2 n}{x} J_{n}(x)=J_{n-1}(x)+J_{n+1}(x)  \tag{34}\\
& J_{n}^{\prime}(x)=\frac{1}{2} J_{n-1}(x)-J_{n+1}(x) \tag{35}
\end{align*}
$$

${ }^{6}$ Arfken, pp. 373-374.
and the Bessel function derivative formula Eq. (26), the following relationship can be derived for the second order derivative.

$$
\begin{equation*}
J_{n}^{\prime \prime}(x)=\left(\frac{n^{2}}{x^{2}}-1\right) J_{n}(x)-\frac{1}{x} J_{n}^{\prime}(x) \tag{36}
\end{equation*}
$$

This equation holds for both real and complex arguments. The substitution of Eq. (36) Into Eq. (33) gives after collecting like terms,

$$
\begin{equation*}
\frac{B_{n}}{A_{n}}=\frac{J_{n}^{\prime}(\lambda a) \lambda a(1-v)+J_{n}(\lambda a)\left[\lambda^{2} a^{2}-(1-v) n^{2}\right]}{-J_{n}^{\prime}(1 \lambda a) i \lambda a(1-v)+J_{n}(i \lambda a)\left[\lambda^{2} a^{2}+(1-v) n^{2}\right]} \tag{37}
\end{equation*}
$$

The Bessel functions with complex arguments may be replaced by Modified Bessel functions using Eq. (20) and Eq. (21).

$$
\begin{equation*}
\frac{B_{n}}{A_{n}}=\frac{J_{n}^{\prime}(\lambda a) \lambda a(1-v)+J_{n}(\lambda a)\left[\lambda^{2} a^{2}-(1-v) n^{2}\right]}{-1^{n} I_{n}^{\prime}(\lambda a) \lambda a(1-v)+i^{n} I_{n}(\lambda a)\left[\lambda^{2} a^{2}+(1-v) n^{2}\right]} \tag{38}
\end{equation*}
$$

After the first order derivatives are eliminated by Eq. (26)
and Eq. (27), the resulting form is then set equal to
Eq. (32). The frequency equation is then obtained by clearing fractions and factoring like terms. The final result is

$$
\begin{array}{r}
2 \lambda a\left[I_{n}(\lambda a) J_{n}(\lambda a)\right]-(1-v)\left[I_{n}(\lambda a) J_{n+1}(\lambda a)+J_{n}(\lambda a) I_{n+1}(\lambda a)\right] \\
=0 \tag{39}
\end{array}
$$

As before the solution consists of an infinite number of eigenvalues, $\lambda_{n m}$, from which the natural frequencies are
able to be found.

Free Edge. The boundary conditions for a circular plate of radius a with a free edge are: ${ }^{7}$
(a) The bending moment at the edge is zero.

$$
\begin{equation*}
M_{r}(a, \theta)=0 \tag{40}
\end{equation*}
$$

(b) The effective shear at the edge is zero.

$$
\begin{equation*}
V(a, \theta)=Q_{r}-\frac{1}{r} \frac{\partial}{\partial \theta}\left(M_{r t}\right)=0 \tag{HI}
\end{equation*}
$$

where

$$
\begin{equation*}
Q_{r}=-D \frac{\partial}{\partial r}\left(\nabla^{2} W\right) \tag{42}
\end{equation*}
$$

and

$$
\begin{equation*}
M_{r t}=(1-v) D\left[\frac{1}{r} \frac{\partial^{2} W}{\partial r \partial \theta}-\frac{1}{r^{2}} \frac{\partial W}{\partial \theta}\right] \tag{43}
\end{equation*}
$$

The first boundary condition has already been evaluated in the previous section. The resulting ratio was given by Eq. (38). The substitution of Eq. (14) into the second boundary condition for a free edge yields,

$$
\begin{array}{r}
-\lambda^{3} J_{n}^{\prime \prime \prime}(\lambda a)-\frac{1}{a} \lambda^{2} J_{n}^{\prime \prime}(\lambda a)+J_{n}^{\prime}(\lambda a) \lambda \frac{1}{a^{2}}\left[1+n^{2}+n^{2}(1-v)\right] \\
\frac{B_{n}}{A_{n}}=\frac{-J_{n}(\lambda a) \frac{1}{a^{3}}\left[2 n^{2}+n^{2}(1-v)\right]}{-i \lambda^{3} J_{n}^{\prime \prime \prime}(i \lambda a)-\frac{1}{a} J_{n}^{\prime \prime}(i \lambda a)-J_{n}^{\prime}(1 \lambda a) 1 \lambda \frac{1}{a^{2}}\left[1+n^{2}+n^{2}(1-v)\right]} \\
+J_{n}(1 \lambda a) \frac{1}{a^{3}}\left[2 n^{2}+n^{2}(1-v)\right] \tag{44}
\end{array}
$$

7 Timoshenko, p. 284.

Using the previously stated relationships for the second order and first order derivatives, and the recursion formule for Bessel functions, an equation for the third order derivative may be derived. It is

$$
\begin{equation*}
J_{n}^{\prime \prime \prime}(x)=\left[\frac{n^{2}}{x^{2}}-1+\frac{2}{x^{2}}\right] J_{n}^{\prime}(x)-\left[\frac{3 n^{2}}{x^{2}}-\frac{1}{x}\right] J_{n}(x) \tag{45}
\end{equation*}
$$

After the elimination of the second and third order derivatives, Eq. (44) can be written as,

$$
\begin{equation*}
\frac{B_{n}}{A_{n}}=\frac{J_{n}^{\prime}(\lambda a) \lambda a\left[\lambda^{2} a^{2}+(1-v) n^{2}\right]-J_{n}(\lambda a)(1-v) n^{2}}{J_{n}^{\prime}(i \lambda a) i \lambda a\left[\lambda^{2} a^{2}-(1-v) n^{2}\right]+J_{n}(i \lambda a)(1-v) n^{2}} \tag{46}
\end{equation*}
$$

The Bessel functions with complex arguments can be replaced by Modified Bessel functions using Eq. (20) and Eq. (21). The resulting form is then set equal to Eq. (38), and the first order derivatives are eliminated by Eq. (26) and

Eq. (27). The final form is the frequency equation for a circular plate with a free edge.

$$
\begin{aligned}
& {\left[J_{n}(\lambda a)\left[\lambda^{2} a^{2}-n(n-1)(1-v)\right]-J_{n+1}(\lambda a) \lambda a(1-v)\right]} \\
& \quad\left[n I_{n}(\lambda a)\left[\lambda^{2} a^{2}-n(n-1)(1-v)\right]+I_{n+1}(\lambda a) \lambda a\left[\lambda^{2} a^{2}-(1-v) n^{2}\right]\right] \\
& \quad-\left[n J_{n}(\lambda a)\left[\lambda^{2} a^{2}+n(n-1)(1-v)\right]-J_{n+1}(\lambda a) \lambda a\left[\lambda^{2} a^{2}+(1-v) n^{2}\right]\right] \\
& \\
& \quad\left[I_{n}(\lambda a)\left[\lambda^{2} a^{2}+n(n-1)(1-v)\right]-I_{n+1}(\lambda a) \lambda a(1-v)\right]=0
\end{aligned}
$$

The solution of Eq. (47), as in the previous cases, consists of an infinite number of eigenvalues, $\lambda_{n m}$, from which the natural frequencies may be found. For the particular
cases of the zero and first order vibrations of a free plate, the first root of Eq. (47) is equal to zero. This peculiarity occurs because the only terms remaining in Eq. (47) when $n$ is equal to zero or one are those which have $\lambda$ as a factor. Thus, $\lambda_{00}$ and $\lambda_{10}$ equal to zero are roots,

Thus the three natural frequency equations are:
(a) Clamped Edge Eq. (28)
(b) Simply Supported Edge
(c) Free Edge
Eq. (47)

The solutions of these equations were found by a numerical iteration technique used on a digital computer. This program is discussed in the last chapter of this text.

Equations of Nodal Diametral Lines
The equation for the displacement in the vertical direction of a point on the midale surface of the plate as a function of position alone was given in the first section of this chapter. A similiar form is given here as

$$
\begin{align*}
W_{n m}(r, \theta)=\left[A_{n} J_{n}\left(\lambda_{n m} r\right)+\right. & \left.B_{n}{ }_{n}\left(i \lambda_{n m} r\right)\right] \\
\bullet & {\left[c_{n} \cos (n \theta)+D_{n} \sin (n \theta)\right] } \tag{48}
\end{align*}
$$

where $\lambda_{\mathrm{nm}}$ and $\mathrm{W}_{\mathrm{nm}}$ replace $\lambda$ and $W$ of Eq. (14). It can be shown that the number of nodal diameters corresponds to
the value of $n$, which is the order of the frequency equation. For a specific value of $\lambda_{n m}$ and $r$, Eq. (48) can be written as

$$
\begin{equation*}
W_{n}(\theta)=R_{n}\left[C_{n} \cos (n \theta)+D_{n} \sin (n \theta)\right] \tag{49}
\end{equation*}
$$

where $R_{n}$ is a constant equal to the value of the first bracketed quantity of Eq. (48). Equation (49) can also be written in the following form.

$$
\begin{equation*}
W_{n}(\theta)=K_{n} \cos (n \theta-\alpha) \tag{50}
\end{equation*}
$$

where

$$
\begin{equation*}
K_{n}=R_{n} \sqrt{c_{n}^{2}+D_{n}^{2}} \tag{51}
\end{equation*}
$$

and

$$
\begin{equation*}
\alpha=\arctan \left[D_{n} / C_{n}\right] \tag{52}
\end{equation*}
$$

The displacement $W$ will be equal to zero when the angle in Eq. (50) is equal to an odd integer multiple of $\pi / 2$, that is

$$
\begin{equation*}
(n \Theta-\alpha)=k(\pi / 2) \quad \text { for } \quad k=1,3,5, \ldots \tag{53}
\end{equation*}
$$

or

$$
\begin{equation*}
\Theta=\frac{k \pi}{2 n}+\frac{\alpha}{n} \tag{54}
\end{equation*}
$$

where $0 \leqslant \theta \leqslant 2 \pi$ and $k$ and $n$ are integers. Then as an illustration $n$ is chosen to be unity, and furthermore, the angle $\alpha$ is chosen to be zero. A radial node line would then occur at

$$
\begin{equation*}
\theta=\pi / 2, \quad 3 \pi / 2 \tag{55}
\end{equation*}
$$

Similarly, if $n$ were equal to two, nodal lines will occur at

$$
\begin{equation*}
\theta=\pi / 4, \quad 3 \pi / 4, \quad 5 \pi / 4,7 \pi / 4 \tag{56}
\end{equation*}
$$

Thus, it is seen that the number of nodal diametral lines corresponds to the value of $n$, the order of the equation. It is noted that Eq. (54) does not apply when $n$ is equal to zero, since Eq. (48) is then no longer a function of $\theta$, and there are no nodal diameter lines present.

## Equations of Nodal Circles

If the value of $\theta$ is held constant in Eq. (48) it can be written as

$$
\begin{equation*}
W_{n m}(r)=\left[A_{n} J_{n}\left(\lambda_{n m} r\right)+B_{n} J_{n}\left(i \lambda_{n m} r\right)\right] \cdot K_{1} \tag{57}
\end{equation*}
$$

To find the radii of the nodal circles, this equation is set equal to zero. The constant $K_{1}$ can then be divided out since $\theta$ may be chosen such that it does not give a nodal diameter line. The resulting equation is

$$
\begin{equation*}
A_{n} J_{n}\left(\lambda_{n m} r\right)+B_{n} J_{n}\left(i \lambda_{n m} r\right)=0 \tag{58}
\end{equation*}
$$

or

$$
\begin{equation*}
\frac{B_{n}}{A_{n}}=\frac{-J_{n}\left(\lambda_{n m} r\right)}{J_{n}\left(i \lambda_{n m} r\right)} \tag{59}
\end{equation*}
$$

The Bessel function of a complex argument can be expressed as a Modified Bessel function using Eq. (20). Then Eq. (59) can be written as

$$
\begin{equation*}
\frac{B_{n}}{A_{n}}=e^{-1^{-n}} \frac{J_{n}\left(\lambda_{n m} r\right)}{I_{n}\left(\lambda_{n m} r\right)} \tag{60}
\end{equation*}
$$

This particular form is desirable because the ratios $B_{n} / A_{n}$ have been found in the derivation of the frequency equations for each edge condition. Both boundary conditions for each of the three plate edge conditions were solved for this ratio. Equation (60) can be equated to one of these ratios for each one of the edges.

Clamped Edge. The equating of Eq. (60) to Eq. (24) yields

$$
\begin{equation*}
\frac{J_{n}\left(\lambda_{n m} r\right)}{I_{n}\left(\lambda_{n m} r\right)}=\frac{J_{n}\left(\lambda_{n m} a\right)}{I_{n}\left(\lambda_{n m} a\right)} \tag{61}
\end{equation*}
$$

or

$$
\begin{equation*}
J_{n}\left(\lambda_{n m} r\right) I_{n}\left(\lambda_{n m} a\right)-I_{n}\left(\lambda_{n m} r\right) J_{n}\left(\lambda_{n m} a\right)=0 \tag{62}
\end{equation*}
$$

After substituting the values of $\lambda_{n m}$, which have been found for a clamped plate, into Eq. (62), the values of $r$ for which the equation equals zero may be found. These values are the radii of concentric nodal circles. For each $\lambda_{n m}$ there will be $m$ values of $r$ which satisfy the equation.

Simply Supported Edge. The equation for the nodal radil of a plate with simply supported edge is the same as that for a clamped edge. This is the case because both share the same boundary condition, that is, the displacement at
the edge is equal to zero. The values of $\lambda \mathrm{nm}$ used in this equation are those which satisfy the frequency equation of a simply supported plate. Equation (62) may be written again here noting that the $\lambda_{\mathrm{nm}}$ are not the same as those for a clamped plate.

$$
\begin{equation*}
J_{n}\left(\lambda_{n m^{r}}\right) I_{n}\left(\lambda_{n m}^{a}\right)-I_{n}\left(\lambda_{n m}^{r}\right) J_{n}\left(\lambda_{n m}^{a}\right)=0 \tag{63}
\end{equation*}
$$

Free Edge. To find the radii of the nodal circles of a plate with a free edge Eq. (60) is equated to Eq. (38), which was derived from the condition that the moment at the edge was zero.

$$
-i^{-n} \frac{J_{n}(\lambda r)}{I_{n}(\lambda r)}=\frac{J_{n}^{\prime}(\lambda a) \lambda a(1-v)+J_{n}(\lambda a)\left[\lambda^{2} a^{2}-(I-v) n^{2}\right]}{-i^{n} I_{n}^{\prime}(\lambda a) \lambda a(I-v)+i^{n} I_{n}(\lambda a)\left[\lambda^{2} a^{2}+(1-v) n^{2}\right]}(64)
$$

The first order derivatives can be eliminated by Eq. (26) and Eq. (27).

$$
\begin{equation*}
\frac{-J_{n}(\lambda r)}{I_{n}(\lambda r)}=\frac{J_{n}(\lambda a)\left[\lambda^{2} a^{2}-n(1-v)(n-1)\right]-J_{n+1}(\lambda a) \lambda a(1-v)}{I_{n}(\lambda a)\left[\lambda^{2} a^{2}+n(1-v)(n-I)\right]-I_{n}(\lambda a) \lambda a(1-v)} \tag{65}
\end{equation*}
$$

For simplicity of calculation the subscripts nm are omitted from the two preceding equations. After clearing the fractions and simplifying the final equation for the nodal radii of a free plate is, with the subscripts replaced,

$$
\begin{align*}
J_{n}\left(\lambda_{n m} r\right) & {\left[I_{n}\left(\lambda_{n m} a\right)\left[\lambda_{n m}^{2} a^{2}+n(1-v)(n-1)\right]-I_{n+1}\left(\lambda_{n m} a\right) \lambda_{n m} a(1-v)\right] } \\
& +I_{n}\left(\lambda_{n m}\right)\left[J_{n}\left(\lambda_{n m} a\right)\left[\lambda_{n m}^{2} a^{2}-n(1-v)(n-1)\right]\right. \\
& \left.-J_{n+1}\left(\lambda_{n m} a\right) \lambda_{n m} a(1-v)\right]=0 \tag{66}
\end{align*}
$$

The values of $\lambda_{\mathrm{nm}}$ which satisfy the frequency equation for a free plate are substituted into Eq. (66), and the radil of the nodal circles can then be found.

## Ratio Method for Nodal Circies

A method utilizing the ratios of the natural frequency eigenvalues may be employed to find the radii of the nodal circles of vibrating plates. It can be shown that for each $\lambda_{n m}$ there are $m$ values of $r$ which satisfy the nodal circle equations. For the clamped and the simply supported edges the minimun value which $m$ can have is unity, because the edge must be a node. However, beginning with the second order, the free plate is capable of assuming a mode shape without any nodal circles. Thus, $m$ is equal to zero.

The maximum value which $r$ can have is $a$, the radius of the plate. For the cases of the clamped and simpiy supported plates, the edge will always be a node, or $r$ equal to $a$ is a solution to the nodal circle equations. The value of the first root of the $n \frac{\text { th }}{}$ order equation is $\lambda n 2^{a}$. When $m$ is equal to two, $\lambda n 2^{a}$ is a solution. However, a root will aiso occur when $r$ is such that the product $\lambda_{n 2^{r}}$ is equal to $\lambda_{n 1}$. Since $\lambda_{n 2}$ is greater than $\lambda_{n 1}$, and $r$ is less than $a$, this equality is known to be
attainable. Thus, for $\lambda_{n 2}$ there is one nodal circle present in addition to the edge. It follows that for each $\lambda_{n m}$ a root will occur at $\lambda_{n m}{ }^{a}$, for the edge, and whenever the product $\lambda_{n m} r$ is equal to one of the previous products $\lambda_{n m-1}{ }^{a}, \lambda_{n m-2^{a}} \cdots \lambda_{n 1^{a}}$. Therefore, there are $m$ values of $r$ which satisfy the nodal circle equations for each $\lambda_{n m}$. This relationship between the roots may be used to produce a scheme to find the radil of the nodal circles. For a given value of $n$, the following equalities are determined for the $m$ values of $\lambda_{n m}$.

$$
\begin{array}{r}
\frac{m=1}{a \lambda_{n 1}}=r_{22 \lambda_{n 2}}=r_{33 \lambda_{n 3}}=r_{44 \lambda_{n 4}}^{m=3} \\
a \lambda_{n 2}=r_{32 \lambda_{n 3}}=r_{43 \lambda_{n 4}} \\
a \lambda_{n 3}=r_{42} \lambda_{n 4}  \tag{67}\\
a \lambda_{n 4}
\end{array}
$$

Since the values of $\lambda_{n m}$ have been determined from the frequency equations, the radil of the nodal circles may be found from the ratios given in the group of equations called Eq. (67). For the first case,

$$
\begin{equation*}
r_{22}=\frac{\lambda_{n 1} a}{\lambda_{n 2}} \tag{68}
\end{equation*}
$$

and in the general case,

$$
\begin{equation*}
r_{m, k}=\left[\frac{\lambda_{n, m-1}}{\lambda_{n, m}}\right]^{r}{ }_{m-1, k-1} \quad \text { for } m \geq 1, \text { and } k \geq 1 \tag{69}
\end{equation*}
$$

where $r_{m l}=a$, for all $m$, for the clamped and simply supported edge. Thus, once the natural frequency eigenvalues are known, the radii of the nodal circles may be found from them directly.

The case of the free edge is more difficult to handle than the two preceding edge conditions. Since the edge is not constrained, its displacement is not equal to zero. Therefore $r$ equal to a is not a solution to the equation for the nodal radii of a free plate, that is, Eq. (66). In order to use the above scheme for a free plate, $r_{m l}$ must be evaluated for each value of $\lambda_{n m}$. Once these values are known, the same procedure may be followed to find the nodal radii. The values of $r_{m}$ are obtained from Eq. (66).

Due to the unconstrained boundary, the first mode does not exist for the zero order vibration or for the first order vibration. It was noted in the previous section that $\lambda_{00}$ and $\lambda_{10}$ are equal to zero. This phenomena can also be explained by observing the physical characteristics of a vibrating free plate, and the behavior of Eq. (66). The first mode of the zero order vibration would have the center point
as a node since the edge is free. However, this is clearly impossible for the zero order case, since both $J_{0}(0)$ and $I_{0}(0)$ are equal to unity. Equation (66) cannot equal zero uniess $\lambda_{00}$ equals zero. Thus, when there are no nodal diameters, at least one nodal circle must be present during vibration. The first mode of the first order vibration would consist of one nodal diameter and no nodal circles. This situation is physically impossible, because the ends of the plate are unconstrained. It is analogous to the vibration of a free rod in an unsymmetrical mode with a node at the middle, and no other nodes present. The physical reasoning can be confirmed in both cases by the actual calculation of the first root of Eq. (66) with $n$ equal to zero and one. The first root for both orders is different from zero and a, thus indicating the presence of a nodal circle. The radius of the first nodal circie is given as 0.6802a, for the zero order vibration, and 0.781a, for the first order vibration. 8
${ }^{8}$ John Prescott, Applied Elasticity (New York, 1961), pp. 588,596.

## BESSEL FUNCTIONS

The evaluation of Bessel functions of the first kind and Modified Bessel functions of the first kind was accomplished by using four separate methods. Each method was found to have a specific range of arguments for which accuracy could be maintained at eleven significant figures. Overlapping values were found to insure that this degree of accuracy was retained when transferring from one method to the next. The four methods used were:
(a) Infinite Series
(b) Asymptotic Series
(c) Recursion Formula
(d) Approximate Numerical Method

## Infinite Series

The infinite series defining the Bessel function of the first kind is ${ }_{\infty}^{1}$
$J_{n}(x)=\sum_{s=0}^{\infty} \frac{(-1)^{s}}{s!(n+s)!}\left[\frac{x}{2}\right]^{n+2 s}$
and the series for the Modified Bessel function of the first kind is ${ }^{2}$
${ }^{1}$ Arfken, p. 372.
2
Ibid., p. 397.

$$
\begin{equation*}
I_{n}(x)=\sum_{s=0}^{\infty} \frac{1}{s!(n+s)!}\left[\frac{x}{2}\right]^{n+2 s} \tag{2}
\end{equation*}
$$

Both of these series are useful if the value of the argument $x$ is nearly equal to the order $n$. If the argument is much greater than or less than the order, then the rates of convergence of both series are very slow, and a enormous number of terms are required to give acceptable accuracy.

## Asymptotic Series

In order to circumvent the difficulty posed when the argument is large relative to the order, the following Asymptotic expansions were used. ${ }^{3}$

$$
\begin{align*}
J_{n}(x)=\left[\frac{2}{\pi x}\right]^{1 / 2}\left[P_{n}(x)[ \right. & \left.\cos x-\left[n+\frac{1}{2}\right] \frac{\pi}{2}\right] \\
& \left.+Q_{n}(x)\left[\sin x-\left[n+\frac{1}{2}\right] \frac{\pi}{2}\right]\right] \tag{3}
\end{align*}
$$

where

$$
\begin{aligned}
& P_{n}(x)=1-\frac{\left(4 n^{2}-1\right)\left(4 n^{2}-3^{2}\right)}{2!(8 x)^{2}} \\
&+\frac{\left(4 n^{2}-1\right)\left(4 n^{2}-3^{2}\right)\left(4 n^{2}-5^{2}\right)\left(4 n^{2}-7^{2}\right)}{4!(8 x)^{4}}
\end{aligned}
$$

and

$$
Q_{n}(x)=-\frac{\left(4 n^{2}-1\right)}{1!(8 x)}+\frac{\left(4 n^{2}-1\right)\left(4 n^{2}-3^{2}\right)\left(4 n^{2}-5^{2}\right)}{3!(8 x)^{3}} \cdots(5)
$$

3
Ibid., p. 405.
and

$$
\begin{equation*}
I_{n}(x)=C_{n}(x) e^{x}\left[\frac{1}{2 \pi x}\right]^{1 / 2} \tag{6}
\end{equation*}
$$

where

$$
\begin{equation*}
c_{n}(x)=1-\frac{\left(4 n^{2}-1\right)}{1!(8 x)}+\frac{\left(4 n^{2}-1\right)\left(4 n^{2}-3^{2}\right)}{2!(8 x)^{2}} \cdots \tag{7}
\end{equation*}
$$

If the number of terms is taken to be greater than a certain value specified for each order by the relationship,

$$
\begin{equation*}
k>\frac{1}{4}(2 n-5) \tag{8}
\end{equation*}
$$

then the error becomes smaller than the first term which is 4 omitted. The minimum error will be obtained at the smallest term. Thus, each term must be compared to the previous one. Once the terms begin to increase in value accuracy will be lost.

The overlap area between the infinite series and the asymptotic expansion becomes smaller as the order increases. In fact, after the twentieth order vacant areas occur, that is, arguments for which Bessel functions cannot be accurately found by either method.

4
Eugene Jahnke and Fritz Emde, Tables of Functions with Formulae and Curves 4th ed. (New York, 1945), p. 137-138.

Recursion Formula
Since the two previous methods give excellent results for the lower orders, a technique was devised to find the higher order values from the zero and first order values. The infinite series is used for arguments less than thirteen, and the asymptotic series for arguments which are greater than or equal to thirteen. The Bessel functions of higher orders can then be found by using the appropriate recursion formulas. 5 These formulas are obtained from the standard Bessel function recursion formulas by replacing $n$ by $n-1$.

$$
\begin{equation*}
J_{n}(x)=\frac{2(n-1)}{x} J_{n-1}(x)-J_{n-2}(x) \tag{9}
\end{equation*}
$$

and

$$
\begin{equation*}
I_{n}(x)=I_{n-2}(x)-\frac{2(n-1)}{x} I_{n-1}(x) \tag{10}
\end{equation*}
$$

By starting with the zero and first orders any higher order value can be found by using these recursion formulas to advance one order for each cycle. To find the Bessel function of the tenth order, for example, nine cycles would have to be made, that is one cycle to find the value for each of the orders from the second to the tenth inclusively.
${ }^{5}$ Arfken, pp. 373, 397.

## Approximate Numerical Method

The recursion formulas work well if the order is less than the argument, however, when the argument is less than the order a rapid accumulation of round off errors destroys the accuracy. This problem has plagued the users of Bessel function tables for many years. Most tables offer a large amount of values for arguments which are greater than the order. As the order increases a greater number of arguments were omitted. Until very recently this problem was insurmountable, and these values were never used.

An analysis of the situation shows the reason for this round off error is the fact that $J_{n}(x)$ and $I_{n}(x)$ are decreasing functions of $n$ if $n$ is greater than $x$. The Bessel function of each succeeding order is smaller than its predecessor, and eventually its contribution is lost. However, a recursion process may be carried out in the direction of decreasing $n$ and still maintain accuracy. A scheme for a numerical approach to evaluating Bessel functions by this reverse recursion technique is given by F.W.J. Olver. ${ }^{6}$ The procedure is as follows. To evaluate $_{\text {Abramowitz, pp. }}$ 385-386.
the Bessel function of the first kind of order $p$, for some argument $x$, such that $p$ is greater than $x$, the value of a test order $q$ must first be chosen. Then $J_{q}(x)$ is set equal to zero, and $J_{q-1}(x)$ is set equal to unity. These two values are then used to initiate the reverse recursion process. The formula used is obtained by replacing $n$ by $n+2$ in Eq. (9) to give,

$$
\begin{equation*}
J_{n}(x)=\frac{2(n+1)}{x} J_{n+1}(x)-J_{n+2}(x) \tag{II}
\end{equation*}
$$

Each value of $J_{n}(x)$ obtained from Eq. (Il) is stored or retained until $J_{p}(x)$ is reached. The number of digits in this trial value for $J_{p}(x)$ is the number of accurate digits In the final result, that is the actual value of $J_{p}(x)$. Thus, the test order $q$ must be chosen large enough to yield the desired number of accurate digits. If the number of digits in the trial value $J_{p}(x)$ is equal to the number of accurate digits needed in the actual value of $J_{p}(x)$, then the value of $q$ is sufficiently large. If this is not the case, then a larger value of $q$ is used, and the process is repeated until the required number of digits is achieved. The recursion process is continued until $J_{0}(x)$ is found. To find the actual value of $J_{p}(x)$, the trial value for $J_{p}(x)$ found above is multiplied by a normalization factor $K$.

This factor $K$ is found by substituting the trial values into the following relationship.

$$
\begin{equation*}
\frac{1}{K}=J_{0}(x)+2 J_{2}(x)+2 J_{4}(x)+2 J_{6}(x)+\ldots \tag{12}
\end{equation*}
$$

The test order $q$, by actual evaluation, was found to be a function of both the order and the argument. The value of $q$ necessary to maintain eleven digits in the trial value of $J_{p}(x)$ was found to be large if $x$ approached $p$, and not much greater than $p$ itself when $p$ was greater than $x$. The minimum value of $q$ was approximately $p+15$ for all orders.

The Modified Bessel function of the first kind is treated in a similar manner. The procedure is the same except the relationship for the normalization factor $K$ is

$$
\begin{equation*}
\frac{e^{x}}{K}=I_{0}(x)+2 I_{1}(x)+2 I_{2}(x)+2 I_{3}(x) \quad \ldots \tag{13}
\end{equation*}
$$

where $e$ is the base of the natural logarithms.

Computer programs were devised to evaluate the Bessel functions by the recursion formula technique, and by the approximate numerical method. The range of arguments for which these methods give accurate results had to be evaluated for each order, and an overlap area had to be found between the two methods for each order. The approximate
numerical technique using the reverse recursion method was found to be applicable to all arguments. However, if the argument was greater than the order, the test order $q$ was very large, and the calculation by this method is time consuming. In this area the direct recursion formulas are more efficient than the reverse technique. A combination of the two methods gives the best accuracy in the least amount of time.

The minimum arguments which have to be reached before the direct recursion formulas can be used were found for each order, and a plot was made of the straight line envelope of these points. This was performed for both types of Bessel functions, and the results are given in Fig. (I) on page 36. The calculation of the Bessel functions for each order begins with the approximate method. When the value of the argument is greater than the transfer point for that particular order, the calculations are shifted to the direct recursion method. The empirical equations of the straight line envelopes of these transfer points were found to be:

$$
\begin{equation*}
\text { Transfer Point }=\frac{4}{7}(\text { Order }+35) \tag{14}
\end{equation*}
$$

for the Bessel function of the first kind, and Transfer Point $=3.88$ (Order +1.94 )
for the Modified Bessel function of the first kind. Both of these empirical relationships are applicable for orders which are less than or equal to thirty-three, since that was the maximum order for which the transfer points were evaluated. Bessel functions of arguments which are to the left of the transfer point line in Fig. (I) are evaluated by the approximate numerical method. If the argument is to the right of the line, the recursion formulas are used. The line designated $J_{n}(x)$ is the transfer point line for the Bessel function of the first kind, and the line designated $I_{n}(x)$ is that for the Modified Bessel function of the first kind.
36.

Fig. (1) Bessel function subprogram transfer points.

Bessel Function Subprogram
The Bessel function subprogram is composed of four main divisions, that is, one for each of the four methods discussed in the previous chapter. Each one of these is composed of two subdivisions to find $J_{n}(x)$ and $I_{n}(x)$. Thus, there are eight separate programs used to compute the Bessel function values. The selection of the proper technique is based on both the order and the argument. A flow chart of the Bessel function subprogram is given in Fig. (2) on page 39, and a copy of the actual program is given in the Appendix. This program may be used to calculate the value of the Bessel function, and the Modified Bessel function of the first kind of any argument to eleven digits accuracy for the first thirty-three orders. These four methods may be used for higher orders, but the values of the Modified Bessel function may become exceedingly large, and care must be taken to avoid exceeding the capacity of the computer.

The error of each method of finding the Bessel functions was restricted to be less than 0.00000000001 . A detailed
comparison of values yielded overlap regions among the four different methods. All the values in these overlap regions were checked to agree to eleven digits, and they were also checked with Bessel function tables wherever possible. This agreement of values obtained by totally different methods insures the uninteruption of accuracy when transferring from one method to the other. It also provides an opportunity to check the reliability of the expressions used to evaluate the error of each of the four methods.

## Main Program

The main program consists of an iteration procedure which evaluates the roots of an equation by searching for a sign change of the function, and narrowing the interval of arguments between sign changes until the root is reached. In this scheme an interval of some specified length is chosen, and the value of the function is noted at the starting point and the end point. For this case, the function is the value of the right side of the frequency equation. Only those arguments which give the function a zero value are solutions to the frequency equation. The sign of the function at each of the two points is compared. If the function exhibits a sign change, a root is present in that

interval. The function is then evaluated at the midpoint of the interval, and its sign is compared to each of the end points. The half interval which contains the sign change is taken as the new interval, and the process is repeated. However, if the sign at the starting point is identical to that of the end point then a new interval of the same length is chosen with the end point of the previous interval taken as the starting point of the new interval. The above process of comparing signs is repeated, and the entire procedure is continued until a root is established. Since the halving process only approximates the roots, some criteria must be introduced to decide which values are considered to be roots. In this program an argument is considered as a solution if either the value of the function corresponding to it is in absolute value less than 0.0000000001 , or the length of the interval has decreased to less than this amount. This situation indicates the occurrence of a sign change within the interval between two arguments which differ by less than 0.0000000001 . The end point of this interval is chosen as the root, and it is also used as the starting point of the next interval, so that this sign change is not considered twice.

An educated guess must be made of the frequency of occurrence of the roots, so that the interval length is chosen to avoid the inclusion of more than one root. In this program the interval length was chosen to be one unit to eliminate the possibility of double roots within a single interval. This value was used because Bessel functions of the first kind are approximately periodic with a period nearly equal to $2 \pi$. The frequency equations exhibit a similar behavior, since the Modified Bessel function of the first kind is divergent. Thus, the periodicity is entirely dependent upon the Bessel function of the first kind.

A flow chart of the main program is given in Fig. (3) on page 42. The suffixes $L$ and $R$ refer to the left and right of the interval, and $\operatorname{FUNCT}(X)$ refers to the function evaluation subprogram, which is analyzed in the next section.

## Function Evaluation Subprogram

In order to evaluate the function used in the main program, the values of the Bessel functions must first be obtained from the Bessel function subprogram. These values are then substituted into the frequency equation, which yields the value of the required function. The subprogram

Fig. (3) Main program flow chart.

Fig. (3) continued.
43.

which contains the frequency equation is called SUBROUTINE EPSLON. The solution of the frequency equation for each boundary condition was accomplished by using the same main program and Bessel function subprogram for each, but in the SUBROUTINE EPSLON only the specific frequency equation for each edge condition was used.

A single function subprogram called FUNCT(X) was used to call the other two subprograms- BESSEL and EPSLON. It allows for the proper selection of the dummy variables which are used in the subroutines, and it facilitates an easy method of transferring control to a series of subprograms. A single "Function" statement will result in the evaluation of all the necessary Bessel functions, and the calculation of the value of $\operatorname{FUNCT}(\mathrm{X})$ to be returned to the main program. It eliminates the necessity of having a series of "Call" statements through out the main program with a different set of variables in each one.

Accuracy of Results
The accuracy of the entire program was maintained at ten significant digits. This was done by imposing the previously stated criteria for defining the value of an argument as a root. Since the only errors which could occur in
the computation are round off errors, it can be shown that this control value represents the actual error of the results. All calculations done prior to the evaluation of the function are accurate to eleven significant figures, since the only calculations performed were the evaluation of the Bessel functions, and these are specified to have this accuracy.

Round off error may be produced in the evaluation of the function in the subprogram titled EPSLON. However, this computation involves only one equation, and the number of operations is not so great as to introduce a round off error large enough to have any effect on the tenth digit of a sixteen digit number. It must also be noted that this calculation is performed only once for each argument, and the error is not accumulated during the iterations, since the Bessel functions are independently calculated for each argument. Some round off error is produced in the main program. However, the only calculation performed is the division of the interval in half, and this computation will also have no effect on the tenth digit of a sixteen digit number. Thus, the only factor which has any detectable effect upon the accuracy of the results is the setting of the control
46.
value to determine when an argument is a root. Since this value was chosen to be 0.0000000001 , the results are accurate to ten significant figures.

## CONCLUSIONS AND RESULTS

The eigenvalues of the natural frequency equation are tabulated for three edge conditions: clamped; simply supported; free. The first twenty-six roots of the first twenty-six orders were found with Poisson's ratio equal to 0.300. The roots of the lower order vibrations are in good agreement with existing results to the degree of accuracy used at the time. Tables of these frequency values given by other authors are also listed here.

In the evaluation of the natural frequencies ten digit accuracy was maintained through out the program. The Bessel function subprogram may be used to find the solutions of other problems which require the evaluation of Bessel functions up to the thirty-third order. The values of higher order Bessel functions may be found if the transfer points for these orders are obtained.
