## ABS TRACT

A model is proposed for the reactions occurring when an aqueous $30 \%$ lactic acid solution i.s contacted with a primary alcohol, normal butanol. Kinetic and equilibrium data for the esterification reactions of monomeric lactic acid and dimeric lactic acid were determined in a series of experiments using an ideal overflow backmix reactor. The variables studied were reaction temperature and catalyst concentration.

It was determined that the significant reactions occurring within this system are the esterification of monomeric lactic acid with n-butanol and lie esterfication of dimerio lasiac acia with a-butanol. Other roections that may be postulated to occur within the system are negligible.

The data is successfully correlated using this reaction model. Rate constants were evaluated at three temperature levels and catalyst levels ranging from zero to 44 moles/liter. The observed rate constants vary linearly with catalyst concentration. The Arrhenius parameters for the reactions were determined. The activation energy and frequency factor for the uncatalyzed formation of butyl lac-
tate were found to be $21220 \pm 715 \mathrm{cal}$ and $(6.258 \pm 0.97) \times 10^{8}$ 1iter/mole-second, respectively. The activation enersy and frequency factor for the catalyzed formation of butyl lactate were found to be $10870 \pm 650 \mathrm{cal}$ and $8.91 \pm 1.101$ iter $^{2} / \mathrm{mole}^{2}-\sec$ ondmmole of cat, respectively. The activation energy and frequency factor for the uncatalyzed formation of butyllactyllactate were found to be $17580 \pm 300$ cal and $(1.303 \pm 0.080) \times 10^{6}$ liter/mole-sec, respectively. The activation energy and the frequency factor for the catalyzed formation of butyllactyllactate were found to be $7980 \pm 645 \mathrm{cal}$ and $(4.54 \pm$ $0.55) \times 10^{-2}$ Iiter ${ }^{2} /$ mole-sec-mmole catalyst.

The equilibrium constant for the butyllactate formation reaction was determined to be $3.13 \pm 0.16$. The equilibrium constant for the butyllactyllactate formation reaction was determined to be $2.75 \pm 0.15$.

Equilibrium constants were evaluated at $25^{\circ} \mathrm{C}$ and were assumed to be constant with respect to temperature and catalyst concentration.

Kinetic and equilibrium data for the hydrolysis of dimeric lactic acid were determined in a series of experiments using an jideal overflow backmix reactor. The variables studied were reaction tem-
perature and catalyst concentration.

Rate constants were evaluated at three temperature levels and catalyst levels ranging from zero to 35 moles/liter. The observed rate constants vary linearly with catalyst concentration. The Arrhenius parameters for the reaction were determined. The activation energy and frequency factor for the uncatalyzed hydrolysis of lactyllactic acid were found to be $22930 \pm 1617 \mathrm{cal}$ and (6.307 $\pm 1.83$ ) $x 10^{8}$ 1iter/mole-second, respectively. The activation energy and frequency factor for the catalyzed hydrolysis of lactyllactic acid were found to be $12360 \pm 219$ cal and $6.821 \pm 0.253$ 1iter ${ }^{2}$ mole-seconmole of catalyst, respectively.

The equilibrium constant for the hydrolysis of lactyllactic acid was determined to be $1.27 \pm 0.07$. The equilibrium constant was evaluated at 25 C and was assumed to be temperature and catalyst independent.

## ACKNOWLEDGMENTS

The author wishes to thank the many people who have contributed both directly and indirectly to the fruitful completion of this dissertation. I express my heartfelt gratitude to the faculty and staff of the Chemical Engineering Department for several years of pleasant association from which I have profited very much both as an engineer and as an individual.

To Dr. Saul I. Kreps, I wish to express my warmest thanks and sincerest appreciation for the guidance and advice that has made my graduate years at N.C.E. the most rewarding years of my academic life. Thank you.

I thank also my loving wife for her patience and understanding through the long days and late nights. My eternal debt to her would take more than a lifetime to repay.

Finally, $I$ wish to dedicate this work to my father who would have liked so much to have seen this day.

> Thank you, R.D.

Robert Dix was born in
on . He received his Bachelor of Science degree in Chemical Engineering from Newark College of Engineering in 1965. In 1966 he received his Master of Science degree from the same institution on a National Defense and Education Act Fellowship. He was granted a National Science Foundation Fellowship and an Esso Industrial Fellowship for one year each for doctoral study at Newark College of Engineering in 1967 and 1968, respectively.

He was a Special Lecturer in Chemical Engineering at Newark College of Engineering. He has worked during the summer as a chemical engineer a* Pittsburg Plate Glass Co., in Newark, New Jersey; Union Carbide, Newark, New Jersey; and Celanese Research Corporation, Summit, New Jersey. Presently, he is employed at Celanese Research Corporation, in Summit, New Jersey.

## CHAPTER I

## Introduction

## A. SCOPE AND PURPOSE OF INVESTIGATION

The object of this work was to determine the rates of the various reactions occurring when a water solution of lactic acid is reacted with normal butyl alcohol. A kinetic determination was made of the rate constants and Arrhenius parameters for the system of esterification reactions.

The mechanistic results obtained from this study should not be restricted to the one alcohol selected for use in this system, but should be generally applicable to any primary alcohol.

The present investigation was initiated by the desire to develop an economical process for purification of technical grade lactic acid obtained by the fermentation route.

## Lactic Acid Production

In recent years there has been a trend of industry away from the purification of fermentation lactic acid. At present, only one company, (Clinton

Corn Processing Company,) is still using the fermentation process.

A new synthetic process for the production of lactic acid has been developed ( $\underline{1}, \underline{14}, \underline{2}$ ) and will undoubtedly bring about the demise of the method of fermentative production in the near future. The motivating force behind this thesis is the final determination of the kinetics of the esterification of water solutions of lactic acid.

A conspicuous feature of the fermentation lactic acid industry is the sale of the acid in varying grades at prices somewhat higher than the cost of the sugars used as raw materials. Since the dilute fermentation liquors of lactic acid are relatively inexpensive, the high cost of the purified grades can only be attributed to difficulties encountered in its purification (22). Purification of Fermentation Acid

The purification of fermentation lactic acid is made difficult by its low vapor pressure, its tendency to undergo self-esterification (23), its similarity in solubility characteristics to water, and the presence of several impurities such as dextrins, proteins, inorganic salts and unfermented
sugars (4, 33, 43, 45, 50).
Several methods of purification procedures have been reviewed by Smith and Claborn (50), who recommend conversion of calcium lactate to methyl lactate, purification of the methyl ester by distillation, and then the hydrolysis of the ester back to the acid (64,65).

Other proposed purification methods include crystallization of the calcium ( $13, \underline{40}, \underline{42}, \underline{64}$ ), aniline ( 8 ), or zinc salts (50,61) ; extraction with a solvent such as isopropyl ether ( $32, \underline{54}, \underline{60}, \underline{29}$ ) ; and, distillation (50) techniques, such as, vacuum distillation ( $34, \underline{52}$ ), steam distillation under reduced pressure ( $\underline{27}, \underline{38}, \underline{39}, \underline{48}, \underline{49}$ ), distillation in a gas stream (41), and passage of superheated steam through condensation polymers of lactic acid (43).

A more detailed review of purification methods used is given by Kaplan (30).

Backhaus (3) obtained the first of a series of patents in 1922 describing an esterification process whereby alcohol, acetic acid, and sulfuric acid were fed into a distilling column and the ester continuously removed. This process was improved upon by subsequent workers (31). Until 1945, almost all continuous esterification column design was
done on an empirical basis, with the factors determining the amount of esterification taking place on a given plate or the number of plates required to produce the desired completeness of reaction and separation not being considered. Leyes and Othmer (36) have shown that with both kinetic data and vaporliquid equilibrium data, it was possible to calculate what was occurring in a continuous esterification column after steady state conditions had been attained. Berman (6) has also approached this problem from a similar point of view.

A preliminary empirical investigation by Dix (18) was performed on a method for the continuous esterification of technical grade (44\%) lactic acid. This is one step in a proposed industrial process for the purification of lactic acid. Technical grade lactic acid was treated with $n$-butyl alcohol in the presence of hydrochloric acid catalyst, to yield the ester, butyl lactate, and water. The water formed and the water present in the initial feed was removed by continuous azeotropic distillation. This water removal served to drive the reaction toward completion and thereby increase the yield of the ester.

The reaction was performed in an overflow back-
mix reactor connected in series with a bubble cap plate distillation column of original design. The reactants were fed into the reactor, the product of which was in turn fed to the distillation column. The greatest amount of reaction occurred in the reactor, with the column serving to drive the reaction to near completion. The azeotrope, (composed of 79 mole per cent water) was cooled and condensed. Phase separation occurred upon condensation, allowing the condensate to be continuously decanted to recycle the alcohol. In this way, almost all of the unreacted butanol feed may be recovered for recycle.

The results showed that equilibrium was approached in the reactor, and that the equilibrium conversion based on the initial feed was exceeded in the column.

The feasibility of this approach to the continuous esterification of lactic acid has clearly been demonstrated. This key step in turn fits into an over-all industrial design for the purification process as outlined by Kaplan (30). In his process:

1. Crude fermentation lactic acid is continuously fed into an esterification column, such as described above, and is esterified by $n$-butyl alcohol.
2. Unreacted alcohol, water and ester are separated from the reaction mixture.
3. Purified butyl lactate is steam-hydrolyzed to yield lactic acid and n-butyl alcohol. The butyl alcohol is recovered and recycled to the esterification column. A column design similar to the esterification column would be required, with kinetic design considerations merely approaching equilibrium from the other direction.

## Continuous Esterification Processes

The major factors involved in the design of columns for the process described are the law of mass action, the laws of kinetics, and the distillation laws, all operating simultaneously. Esterification can occur only when the concentrations of the components give calculated values of the equilibrium ratio which are less than the value of the true equilibrium constant; otherwise, hydrolysis must occur. The kinetics of a homogeneous liquid phase reaction such as the esterification of lactic acid with butyl alcohol, are modelled by the equations governing the rate of reaction and the variation of the rate constant (which varies as a function of the temperature and catalyst concentration). The usual distillation laws may have to be modified since moles of reactants disappear while moles of products appear on each plate. Since these kinetic
considerations are super-imposed on distillation operations, each plate must be treated separately by successive calculations after the number of moles converted has been determined (36).

Due consideration must also be given to the design of the distilla tion operations to drive the reaction toward completion by $\mathrm{sir}_{\mathrm{i}}$ aration of one of the products of the reaction. In the present system, the water formed is distilled overhead to remove it from the reaction zone.

## Reaction Kinetics

In order to design a system such as that described above the kinetics of all possible reactions occurring in the system must be known and the effects of temperature, catalyst concentration, and the mole ratio of the reactants of these kinetics must be available.

Prior investigations ( $5 \underline{66}, \underline{57}, \underline{58}, \underline{30}$ ) into the kinetics of the lactic acid system have yielded inconsis tent results in terms of the effect of initial acid concentration.

In the present work the various possible reaction schemes occurring in the esterification of lactic acid
solution were investigated. Based on a preliminary analysis of experimental data, a preferred reaction scheme was selected. This scheme was fully analyzed with the various kinetic aspects of this system being determined.

## B. BACKGROUND

Lactic acid (Acidum Lacticum, $\alpha$-hydroxypropionic acid, 2-hydroxy propanoic acid, milk acid), $\mathrm{CH}_{3} \mathrm{CHOHCOOH}$, with a formula weight of 90.08 , is the simplest hydroxy acid contining an asymmetric carbon atom. It exists in nature as the two optically active $d$ - and 1-forms and a di-inactive mixture. Lactic acid derives its name from its presence in sour milk where it was first discovered in 1780 by Scheele.
"Scheele allowed milk to ferment for 3 weeks, separated the protein, and added calcium hydroxide to precipitate the phosphate. The calcium lactate remained dissolved and was decomposed with oxalic acid. The filtrate was concentrated and taken up in alcohol. After concentrating the alcohol, the acid lactate was obtained as a thick sirup which could not be distilled or crystallized. From this work, as well as subsequent work, Scheele concluded that the acid was free of acetate and that a new acid had been obtained. Pasteur, in 1867, discovered that the souring of milk was caused by an organized ferment and described the organism which was responsible for the fermentation of sterilized milk. Lister, in 1878, showed that the lactic fermentation is similar to the so-called alcoholic fermentation and is produced by microorganisms which he isolated from sour milk by dilution." (59)

Other early discoveries in the chemistry of lactic acid by such notable chemists as Liebig, Berzelius, Kekule and others, have contributed to the historical and classical development of our knowledge of this widely used acid. Commercial exploitation of this
readily prepared material soon followed. The manufacture and chief uses for lactic acid were developed by Americans; the industry was well established in the U.S. before the manufacture of lactic acid was undertaken in foreign countries. Commercial production of lactic acid was first initiated by Charles Avery, at Littleton, Massachusetts, in 1881 in an attempt to make calcium lactate which was to be used as a substitute for cream of tartar in baking powder.

Many of the recent studies reflect an increasing interest in the synthetic and industrial aspects of lactic acid chemistry and the transformation of abundant carbohydrates-via lactic acid as an inter-mediate-into various industrially valuable products, including chemical intermediates, solvents, plasticizers and resins (24,66).

Lactic acid is a slightly hygroscopic syrup (the racemic mixture more hygroscopic than the optically active isomers), varying in color from colorless to pale yellow (62). The specific gravity of lactic acid is variable, depending on the extent of self esterification it has undergone. It is completely miscible with water, alcohol, and ether, but is insoluble in chloroform. The viscosity and density of aqueous solutions of lactic acid as a function of the concentration are given in Table I. The acid represented by this table is assumed to be the racemic mixture.

As mentioned previously, lactic acid contains an asymmetric carbon atom and exists in the $d-$ and 1-, active and dl-, inactive, forms. Both optical isomers of lactic acid occur naturally, but commercial fermentation acid is mostly the optically inactive form (44). Optically active acids may be prepared under controlled conditions with selected organisms and substrates, or by resolution of the racemic mixture via the zinc ammonium salt or the salt with alkaloids such as morphine (5,25). The two optical isomers have also been separated by fractional

crystallization of pure lactic acid from mixed ethyl ether and ispropyl ether solution (9).

Schopmeyer (59) points out that much confusion exists regarding the nomenclature of the optical isomers, since $d-$ and 1 - have been used to refer to either optical rotation or to configuration. That which shows dextro rotation (commonly known as sarcolactic acid, paralactic acid or d-lactic acid), but the L-configuration is correctly designated by modern nomenclature as $L-(t)$ lactic acid (II). This form of lactic acid is metabolized by the human body. Salts of the dextrorotatory acid are levorotatory.

The enantiomorph, levorotary lactic acid, is properly referred to as $D-(-)$ lactic acid (I). This isomer is not metabolized by the human body. Its salts are dextrorotatory. Heating of either of the optically active lactic acids converts them into the optically inactive racemic forms containing equal proportions of the dextro and levo modifications. The configurational relationships are shown in formulas (I) and (II).

(I) D-(-)-1actic acid

(II) L-(+)-1actic acid

Lactic acid, upon heating, self-esterifies, (see section on Chemistry of Lactic Acid), making the determination of its boiling point impossible at atmospheric pressure, and extremely difficult at lower pressure. The boiling point of lactic acid at reduced pressure has been reported as $119{ }^{\circ} \mathrm{C}$ at 12 mm and $82-85^{\circ} \mathrm{C}$ at approximately 1 mm of mercury.

Since lactic acid is commonly encountered as an aqueous solution, the properties of the lactic acidwater system are extremely important. Dilute aqueous solutions, those with less than approximately $25 \%$ lactic acid, are composed essentially of monomeric lactic acid and water. However, more concentrated solutions show a complex composition due to selfesterification of the acid to longer chain length polylactic acids. The equilibrium composition of aqueous lactic acid then, depends on the concentration (근, 62). Further discussion of the composition of aqueous lactic acid solutions is presented in the section entitled The Chemistry of Lactic Acid.

## D. OCCURRENCE

Lactic acid occurs abundantly in nature in one or another of its three forms. It is a normal constituent in the blood and muscle tissue of animals and the principle acid constituent of sour milk. It has been observed that an abnormally high lactic acid value in human blood is present in some diseases, such as pneumonia, $T B$ and heart failure. Biochemically speaking, lactic acid is also a very important compound; apparently, the energy necessary for muscular activity is normally supplied when glycogen is converted into lactic acid through a complicated series of reactions. Lactic acid has been identified in yeast fermentation and is a component of a by-product of the corn processing industry-corn steep liquor. Some food products containing lactic acid are sauerkraut, pickles, beer, buttermilk, and cheese (44, 66).

## Fermentation Production of Lactic Acid

Lactic acid is industrially produced by the fermentation of refined glucose, hydrolized starch, whey, and molasses. To reduce purification cost, the more refined substrates are used for the production of higher grades of lactic acid. Among the substances proposed as substrates are sulfite waste
liquor, juice of culled citrus fruits, enzymatically hydrolyzed potatoes, acid hydrolyzed wood, mill sawdust, straw, corncobs, extracted beet slices, and Jerusalem artichokes.

Bacteria isolated from souring foods, grains, malt sprouts, or soil may be suitable for commercial production of lactic acid. The nutritional requirements of these organisms are complex. Lactobacillus delbrueckii, for example, illustrates this complexity; it requires 14 amino acids, 4 vitamins, and stimulation by a number of other substances. Addition of small amounts of malt sprouts, corn steep liquor, distillers' grains or solubles, koji, rice bran, peanut oil cake, soybean cake, undenatured milk, or extracts of liver and yeast provide these growth factors. The culture may be maintained by frequent transfer in media of low sugar content such as $5 \%$ corn mash.

A more complete listing of the practices in industrial fermentative production of lactic acid is presented by Schopmeyer in Industrial Fermentations, volume I (59).

Lactobacillus delbrueckii, in one commercial process, is transferred consecutively from test tube to flasks, to seed tanks, and finally to the
wooden or stainless steel fermentor, at all times maintaining an inoculum level of $10 \%$. Culture transfer is made after 16-20 hours of growth at $49^{\circ} \mathrm{C}$. The medium, which consists of $15 \%$ glucose, $0.4 \%$ malt sprouts, $0.25 \%$ diammonium phosphate and $10 \%$ calcium carbonate, is not sterile. Cleanliness, high temperature and low pH are relied on heavily by the industry to restrict and retard contaminants. Butyric bacteria produce volatile acids in addition to a racemase and are therefore considered the most troublesome.

When the fermentation is complete, ( 4 to 6 days required), the concentration of sugar falls to $0.1 \%$ or less and the yield reaches $90-95 \%$. Automatic control of pH is considered advantageous during fermentation since small changes in pH adversely affect the process. Sufficient addition of a calcium carbonate initially or intermittently, as required, helps maintain optimum pH of 5.6-5.8.

Recovery of lactic acid from fermented liquors is a rather difficult process for several reasons. Lactic acid has a low vapor pressure and tends to form anhydrides and undergo self-esterification
when heated and concentrated above 20\%. Extraction techniques are difficult because lactic acid has a solubility similar to water. Froteins, unfermented sugars, inorganic salts, and colored materials are the important contaminants. The protein as a contaminant, is usually removed by coagulation during the complete neutralization of the lactic acid by heating to $90^{\circ} \mathrm{C}$ with excess lime. The insoluble matter is filtered from the system and colored materials and soluble proteins are adsorbed by treatment with charcoal. The purified lactate is then cooled and allowed to crystallize or is concentrated and spray dried. Treatment of a solution of calcium lactate with sulfuric acid followed by filtering off the insoluble calcium sulfate will result in the preparation of lactic acid. The acid may then be repeatedly bleached to attain the desired purity. By treatment with hypochlorites or nitric acid, strong oxidizing agents, some organic impurities in lactic acid can be destroyed.

Theoretically the yield of lactic acid is $100 \%$ of the weight of fermentable sugar; in practice, this yield is never obtained. Presumably a portion of the carbohydrate is metabolized by the organism. In commercial practice, yields of about $85 \%$ are considered normal since further losses occur during
subsequent processing.
The technology of the recovery of lactic acid from the fermentation liquor varies considerably, depending on the grade of acid desired (44).

Crude lactic acid. The crude acid (15\%), can be made by directly acidifying the fermentation liquor obtained from a relatively impure carbohydrate substrate. The quantity and nature of the impurities in the final acid is dependent upon the initial substrate and also on the manufacturing method and the degree of refining (44).

Edible (or Food-Processing) lactic acid. There
are two methods currently being used for the manufacture of edible lactic acid. One method refines the sugar, and the other refines the lactate or lactic acid. The components of the fermentation mash of the first method are a highly refined sugar, a minimum of nutrient material, and a relatively pure calcium carbonate. After the fermentation is completed the mash is acidified with sulfuric acid and the calcium sulfate is removed by filtration. Treatment with vegetable carbon refines and concentrates the light-colored lactic acid. Where applicable, removal of iron and copper is accomplished by precipitation as the ferrocyanides by adding the
stoichiometrical quantity of sodium or calcium ferrocyanide. The carbon and heavy-metal ferrocyanides are filtered out and finally the lactic acid ju diluted to the proper strength (44).

An inexpensive carbohydrate substrate is fermented in the second type of process. The calcium lactate liquor produced by the neutralization may be filtered in order to clarify it, and it may be concentrated to approximately $25 \%$ at the elevated temperature of evaporation. The calcium lactate crystallizes when the solution is cooled. The crystals are filtered or centrifuged to separate them from the liquor, then they are redissolved in water and acidified with sulfuric acid. Filtration removes the calcium sulfate and the light colored lactic acid product is concentrated to the proper strength (44).

An alternative procedure is described by Jenemann (29). This procedure involves the use of isopropy1 ether to extract the lactic acid from the crude solution. The lactic acid is then reextracted from the isopropyl ether with water. This process involves the continuous feeding of concentrated crude lactic acid solution into the top of an extraction tower, while isopropyl ether is introduced at the bottom. The isopropyl ether solution
of lactic acid is removed from the top of the first tower and pumped into a second extraction tower. Here it is passed upwards through a counter current stream of water, removing the lactic acid from the isopropyl ether. The withdrawal of the purified aqueous solution of lactic acid occurs at the bottom of the second tower. The isopropyl ether is pumped from the top of the second tower to the bottom of the first tower for recycling. The acid obtained by this process is of a somewhat higher purity than is required for edible grade. The lactic acid produced by this method has a low concentration of impurities, particularly ash, and frequently enters the market as plastic grade lactic acid (44, 66).

> U.S.P. XVI (formerly N.F.) Lactic Acid. Basically there are three procedures available for the production of U.S. P. lactic acid. U.S.P. grade acid may be a result of the solvent extraction process outlined above. One of the oldest procedures is distillation with steam under relatively high vacuum. The relatively high boiling point of lactic acid results in self-esterification to nonvolatile polyesters so this method is quite expensive. The steam in this distiliation procedure is for the purpose of minimizing this self-esterification. The efficiency
in overcoming entrainment is important in this process. Usually the vapors are led to a particular condenser, where the bulk of distilled acid is stripped, resulting in a condensate of aqueous lactic acid which is $50 \%$ or higher in concentration. Acid remaining in the vapor stream beyond the dephlegmator is recovered by concentration of the final condensate (44).

Perhaps the most practical method for production of this grade of lactic acid involves the formation of the methyl ester as an intermediate ( $\underline{22}, \underline{23}, \underline{25}$ ). First a solution of high acid content is obtained by dehydration; this concentrated solution is subsequent1y esterified with methanol. The esterification may be accomplished by passing the vapors of methanol through the acidified lactic acid at approximately $100^{\circ} \mathrm{C}$, or by refluxing the solution in the presence of a sulfuric acid catalyst. The former method gives higher yields of methyl lactate, since by removal of volatile methyl lactate (in the vapor stream) from the reaction, the equilibrium is favorably shifted. If desired, the methyl lactate may be fractionated and then hydrolyzed completely by boiling in an excess of water and continuously removing the regenerated methanol. The residual
aqueous solution from this treatment is U.S.P. grade lactic acid, which requires some concentration to the final composition.

## E. SYNTHESIS OF LACTIC ACID

Mention should be made at this point of some of the other possible methods for the manufacture of lactic acid. Lactic acid can be synthesized by purely chemical methods such as the degradation of carbohydrates as described by Braun (10). In this method, a suitable carbohydrate, for example sucrose, is heated with a strong alkali, such as sodium hydroxide, at a high temperature and pressure to produce lactic acid.

Another method for synthesizing lactic acid is the heating of carbon monoxide and acetaldehyde in the presence of sulfuric acid at 130 C to 200 C under $900 \mathrm{~atm} . \operatorname{pressure~(37).}$

In addition to the above methods, several other techniques are available for preparing lactic acid, including:

1. Hydrolysis of acetaldehyde cyanohydrin (prepared from acetaldehyde and hydrogen cyanide).
2. Hydrolysis of $\alpha$-chloropropionic acid (pre pared by chlorination of propionic acid).
3. By action of nitrous acid on alanine.
4. By oxidation of propylene glycol, and others. Synthetic methods, however, are generally more

## expensive than fermentation.

One notable exception to the above statement is the process of the Monsanto Company, a relative newcomer in the production of lactic acid. Monsanto, utilizing a proprietary process, produces lactic acid synthetically without the use of an agricultural substrate. Kaplan (30) has speculated that this process proceeds from acetaldehyde to lactonitrile to lactic acid, probably by technique (1) given above.

## F. USES OF LACTIC ACID

Lactic acid is a weak acid with a pleasant sour taste and very little odor. It has good solvent properties, polymerizes readily, and most of its salts are highly soluble. Because of these properties, lactic acid has many uses both in food products and industrially. The uses of lactic acid can therefor be divided into two categories: Food and Non-food.

Food uses. About half of the total annual lactic acid production is of the edible grade. In general, lactic acid can be used as an acidulant in any kind of food or beverage. The properties of lactic acid which make it ideal in a variety of food products are:

1. Its taste is mildly acid as opposed to the sharp biting taste of other food acids.
2. Flavors are not masked or overpowered by it.
3. It prevents deterioration in some foods.
4. Its liquid form makes it ready to use. Because of one or more of the above properties, edible grade lactic acid has found increasing use in animal foods and remedies, bakery products, beer, butter, candy, cheese, dried egg whites, flavoring extracts, jelly, liquid pectin, mincemeat, olives, pickles, sauerkraut, soft drinks, soups and sherberts.

It is also used to adjust the pH of brewery worts to yield proper saccharification and reduce undesirable bacterial fermentations. It is also added to cows milk for baby feeding as an aid in digestion.

As mentioned previously, the first lactic acid process in America was developed for the production of calcium lactate for use in baking powder. It is interesting to note that this is still an important outlet for this acid and considerable quantities of calcium lactate are used in certain baking powders to stabilize them and control the rate of gas evolution. Calcium lactate is also used in certain pharmaceuticals as a source of calcium, a hemostatic and an anti-spasmodic.

Non-food uses. Crude lactic acid has long been used in the leather industry for deliming hides, in vegetable tanning, and for bating and plumping sole leather. It is also the raw material for preparing the esters such as methyl, ethyl, and n-butyl lactates, which are used as solvents. Lactic acid is also used in the acid dyeing of wool and other textile fibers. Other non-food used include applications such as adhesives, electroplating and electropolishing, cleaning and polishing formulation, insecticides and fungicides, oil and water well treating, lithographic
developers, plastics and resins, and special inks and textiles. Lactic acid is useful in neutralizing the alkali catalyst in the manufacture of phenol formaldehyde resins, since a noncrystallizable salt is formed, which does not impair the clarity and strength of the resin. In this application a high purity lactic acid, essentially free of iron is desired.

In recent years several publications have appeared indicating new potential applications of lactic acid and its derivatives. The use of lactic acid as an extender for glycerol in alkyd resins (53) has been described. The preparation of coatings by reaction of polylactic acid with drying oils or with small amounts ( $1-6 \%$ ) of salts of polyvalent metals has been reported (63). The addition of dicyclopentadiene to lactic acid (11) results in a dihydrodicyclopentadienyl ether-ester of lactic acid, which in the presence of driers rapidly absorbs oxygen from the air, to give an insoluble varnishlike film, behaving like a drying oil in this way. By heating to a viscous autoxidizable oil with peroxides this ether-ester $c$ an be polymerized. Many high-boiling lactic esters have been evaluated in a preliminary manner as plasticizers for resins (20, $\underline{24}, \underline{46}, \underline{47}$ ). Lactic and adipic acid mixed
esters of the types $\operatorname{ROOC}\left(\mathrm{CH}_{2}\right){ }_{4} \mathrm{COOCH}\left(\mathrm{CH}_{3}\right) \mathrm{COOR}$ and $\left(\mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{COOCH}\left(\mathrm{CH}_{3}\right) \mathrm{COOR}\right)_{2}$ have been shown to be efficient plasticizers for vinyl chloride copolymers (46). A smooth conversion of lactic acid into methyl acrylate can be accomplished by the following reaction scheme: conversion to methyl lactate, acetylation, and pyrolysis at $550^{\circ} \mathrm{C}(\underline{12}, \underline{51})$.

## G. CHEMISTRY OF LACTIC ACID

## Composition of Lactic Acid

Watson (62) points out that there are many conflicting statements concerning the composition of lactic acid to be found in the literature. This results because lactic acid solutions, except those of less than approximately $25 \%$ concentration, contain two or more compounds besides water.

Because it contains both hydroxyl and carboxyl functional groups, difunctional lactic acid undergoes self-esterification when heated to form linear polyesters as well as lactide. As dilute aqueous lactic acid is concentrated by distillation, the removal of water resulics in a shift in the concentration in favor of self-esterification. The first esterification product is lactyllactic acid. The reaction may be represented as:

$$
\begin{equation*}
2 \mathrm{CH}_{3} \mathrm{CHOHCOOH} \rightleftarrows \mathrm{CH}_{3} \mathrm{CHOHCOOCH}\left(\mathrm{CH}_{3}\right) \mathrm{COOH}+\mathrm{H}_{2} \mathrm{O} \tag{I}
\end{equation*}
$$

As the concentration proceeds, lactide and higher linear esters, that is, the so-called polylactic acids (referred to in earlier literature as "anhydrides") or trimeric, tetrameric, and polymeric lactic acids, are formed ( $\underline{7}, \underline{21}, \underline{25}, \underline{62}$ ). The formation of polylactic
acid may be representer as:

$$
\begin{equation*}
\mathrm{nCH}_{3} \mathrm{CHOHCOOH} \rightleftharpoons \mathrm{HO}\left(\mathrm{CH}\left(\mathrm{CH}_{3}\right) \mathrm{COO}\right)_{\mathrm{n}} \mathrm{H}+\mathrm{n}-1\left(\mathrm{H}_{2} \mathrm{O}\right) \tag{II}
\end{equation*}
$$

The formation of the lactide may be represented as:

Equilibrium between the several components is attained slowly (several weeks) at room temperature, but may be accelerated by the addition of a strong acid catalyst.

A11 of the self-esterification reactions presented above are readily reversible. Therefore, the equilibrium composition of a particular aqueous solution of lactic acid is a function only of the concentration of acid in the solution.

Eder and Kutter (19) studied the composition of aqueous lactic acid solutions as a function of acid concentration and found that solutions below $90 \%$ lactic acid consist of monomeric acid, dimeric acid and water. These results were subsequently
confirmed by Watson (62) and more recently reconfirmed by Kaplan (30). Figure 1 represents the results obtained by Watson in a study of the equilibrium compositions of aqueous solutions of lactic acid.

## Other Reactions of Lactic Acid

Lactic acid undergoes reactions typical of organic acids, and many salts of this acid have been reported. Since lactic acid undergoes esterification readily with many alcohols, numerous lactic esters have been prepared by acid-catalyzed esterification. The esterification is complicated because the esters of polylactic acid are simultaneously produced (25). By using an excess of alcohol in the esterification the formation of ester of polylactic acid can be minimized. The conversion of lactic acid to ester usually occurs in high yields. Esters of polylactic acid, the by-products, are actually a source of lactic acid, so they may be recycled and the ultimate yield of lactic ester is usually high.

Polylactic acid is formed when lactic acid is heated in the presence of catalytic amounts of mineral acid; however, decomposition into acetaldehyde, carbon monoxide, formic acid, and water occurs with larger amounts of mineral acid (25).

Figure 1
RELATION OF TOTAL ACIDITY TO COMPOSITION IN EQUILIBRATED LACTIC ACID SOLUTIONS

When concentrated solutions of the monoesters of lactic acid are heated, particularly in the presence of a mineral acid catalyst, they undergo self-alcoholysis to produce esters of polylactic acid (25):

In these reactions, the lactic esters exhibit behavior similar to lactic acid. Then, similar to the behavior of aqueous lactic acid systems, (where chain lengths greater than the dimer occur only in highly concentrated solutions), it is surmised by this investigator that chain lengths greater than the ester of the dimer, that is, butyllactyllactate may also not be expected to occur, except in extremely concentrated systems.

Lactic esters hydrolize less readily than esters of glycolic acid, but more readily than esters of the fatty acids, such as acetic acid. In general, the lactic esters of secondary alcohols are considerably more resistant to hydrolysis than the esters of corresponding primary alcohols (25). Lactic esters and lactide undergo alcoholysis readily with various alcohols. In the presence of a trace of catalyst, alcoholysis of lactide produces esters
of lactyllactic acid (15), but larger amounts of catalyst yield the monomeric lactic ester. Alcoholysis of methyl lactate with a higher alcohol is an excellent method for preparing lactic esters.

## H. ESTERIFICATION MECHANISMS

## Classification of Mechanisms

Since esterification and hydrolysis can be part of the same equilibrium, information about the mechanism of both may be obtained by a study of one. In the reactions of carboxyl esterification and hydrolysis, a number of distinct mechanisms may be recognized. In general, the bulk of all the suggested mechanisms may be classified (16,17) on three different bases depending upon (I) whether or not the reaction is aci.d- or base-catalyzed, (2) the position of rupture of the carboxyl compound; i.e., whether acyl-oxygen fission or alkyl-oxygen fission occurs. These types of fission are represented below:

Acyl-oxygen fission

Alkyl-oxygen fission
and (3) the reaction kinetics of the steps occurring in the mechanism, i.e., whether the reaction scheme is unimolecular or bimolecular.

The classification described is summarized in Table II. For convenience, basic mechanisms are represented by $B$ and acidic mechanisms by $A$; acyl-

## TARLE II

Mechanism of Carboxyl Hydrolysis and Esterifications
Fission

| Type of Mechanism | Form Attacked | Known <br> Reactions | Acyl- | Alkyl |
| :---: | :---: | :---: | :---: | :---: |
| Basic | $\mathrm{R}^{\prime}-\mathrm{CO}_{2} \mathrm{R}$ | Hydrolysis | - | ${ }^{B}{ }_{A L}{ }^{1}$ |
|  |  |  | ${ }^{B} A{ }^{2}$ | ${ }^{B}{ }_{A L}{ }^{2}$ |
| Acidic | $\begin{gathered} \mathrm{R}^{\prime}-\mathrm{CO}_{2} \mathrm{HR}^{+} \\ \text {or } \\ \mathrm{R}^{\prime}-\mathrm{CO}_{2} \mathrm{H}_{2}^{+} \end{gathered}$ | Hydrolysis <br> and <br> Esterification | ${ }^{\text {A }}{ }^{\text {c }}{ }^{1}$ | ${ }^{A_{A L}}{ }^{1}$ |
|  |  |  | ${ }^{\text {A }} \mathrm{AC}^{2}$ | - |

oxygen and alkyl-oxygen fission are represented by the subscripts $A C$ and $A L$, respectively; and molecularity is indicated by 2 or 1 , depending on whether the reaction is bimolecular or unimolecular. Based on the classifications, eight mechanisms are possible, but only the six that have been observed are entered in the Table (28).

The applicability of these mechanisms may now be examined in light of the subject system; the esterification of lactic acid with a primary alcohol.

Alkaline esterification may be immediately discounted because of the stability of the carboxylate ion. Acid-catalyzed esterification is well known, with the reacting entity being $\mathrm{R}^{\prime}-\mathrm{CO}_{2} \mathrm{H}_{2}^{+}$.

Ingold (28) has examined in depth the relative merits of the remaining three possible esterification mechanisms, and has concluded that in aqueous or alcoholic solvents, such as would be encountered in the system studied here, the $A_{A C}{ }^{2}$, or acidcatalyzed, acyl-oxygen fission, bimolecular mechanism is favored. The reader is referred to Ingold's (28) work for a detailed explanation of the reasoning behind this selection.

The $A_{A C}{ }^{2}$ Mechanism

The mechanistic model consistent with acid catalyzed esterification, the ${ }^{A} A C 2$ mechanism, is envisioned as occurring in the following manner:

1. A preliminary addition of a proton forming a conjugate acidic ion (or oxonium ion).

$$
\begin{equation*}
\mathrm{R}^{\prime}-\mathrm{CO}-\mathrm{OH}+\mathrm{H}^{+} \longrightarrow \mathrm{R}^{\prime}-\mathrm{CO}-\stackrel{+}{\mathrm{OH}_{2}} \quad \text { (fast) } \tag{1}
\end{equation*}
$$

2. This then undergoes an exchange reaction with an alcohol molecule which approaches along the line of the C-0 dipole.

$$
\begin{equation*}
\mathrm{R}^{\prime}-\mathrm{CO}-\stackrel{+}{\mathrm{O}} \mathrm{H}_{2}+\mathrm{HOR} \longrightarrow \mathrm{R}^{\prime}-\mathrm{CO}-\stackrel{+}{\mathrm{OHR}}+\mathrm{OH}_{2} \quad \text { (slow) } \tag{2}
\end{equation*}
$$

3. Loss of a proton to yield the ester.

$$
\begin{equation*}
\mathrm{R}^{\prime}-\mathrm{CO}-\stackrel{+}{\mathrm{O}} \mathrm{OHR} \mathrm{R}^{\prime}-\mathrm{CO}-\mathrm{OR}+\mathrm{H}^{+} \quad \text { (fast) } \tag{3}
\end{equation*}
$$

Certain kinetic characteristics may be predicted from the $A_{A C} 2$ mechanism (28). These are:

1. The rate of esterification should be a function of the concentration of the alcohol.
2. The rate of esterification is a function of the acidity of the system.
3. The rate of esterification is not greatly affected by electropositive substituent in the acyl group.
4. Rates by mechanism $A_{A C}{ }^{2}$ are sensitive to steric hindrance. That is, if either $R$ or $R^{\prime}$ has a branched chain structure and is therefore bulky, it will exert a hindering influence in the formation of the bimolecular complex in (2) and esterification will be accordingly more difficult.
5. The rate should be relatively insensitive to the solvent.

The $A_{A C}{ }^{2}$ reaction mechanism is assumed to be consistent with all of the reactions encountered in this work and will be taken as an accurate depiction of the system. Alcoholysis reactions, being a modification of the hydrolysis reaction, are also described by this mechanism.

## I. DERIVATION OF RATE EXPRESSIONS

Based on the esterification mechanism presented in the previous section, and with the aid of the steady-state approximation, the kinetic rate expression for the reactions actually occurring in this system $c a n$ be derived.

To simplify the presentation of this derivation, the components and intermediates of the reaction system are redefined as follows:

| $\mathrm{R}^{\prime}-\mathrm{CO}-\mathrm{OH}$ | $=\mathrm{A}$ |
| :--- | :--- |
| ROH | $=\mathrm{B}$ |
| $\mathrm{H}^{+}$ | $=\mathrm{C}$ |
| $\mathrm{R}^{\prime}-\mathrm{CO}-\mathrm{OH}_{2}$ | $=\mathrm{D}$ |
| $\mathrm{R}^{\prime}-\mathrm{CO}-\mathrm{OHR}$ | $=\mathrm{R}$ |
| $\mathrm{H}_{2} \mathrm{O}$ | $=\mathrm{W}$ |
| $\mathrm{R}^{2}-\mathrm{CO}-\mathrm{OR}$ | $=\mathrm{P}$ |

Using this key to the identification of components and introducing rate constants, the reaction mechanism may be rewritten as :

$$
\begin{align*}
& \mathrm{A}+\mathrm{C} \underset{\mathrm{k}_{2}}{\stackrel{\mathrm{k}_{1}}{\leftrightarrows}} \mathrm{D}  \tag{4}\\
& \mathrm{D}+\mathrm{B} \underset{\mathrm{k}_{4}}{\stackrel{\mathrm{k}_{3}}{\rightleftarrows}} \mathrm{R}+\mathrm{W}  \tag{5}\\
& \mathrm{R} \underset{\mathrm{k}_{6}}{\mathrm{k}_{5}} \mathrm{P} \tag{6}
\end{align*}
$$

Consistent with the relative rates given by the mechanism, $k_{1}, k_{2}, k_{5}$, and $k_{6}$ are very large, and $k_{3}$ and $k_{4}$ are very small in magnitude.

The intermediate compounds $D$ and $R$ are not detectable in the reaction mixture, but product $P$ is formed as rapidly as product $W$. It may be said then that intermediate $R$ rapidly decomposes to form product $P$.

The rate of formation of products $P$ and $W$ may be written directly from equations (5) and (6) above as the algebraic sum of the rates of formation by all pertinent reactions in terms of the concentration of the individual components, or,

$$
\begin{align*}
& r_{P}=k_{5} C_{R}-k_{6} C_{P} C_{C}  \tag{7}\\
& r_{W}=k_{3} C_{D} C_{B}-k_{4} C_{R} C_{W} \tag{8}
\end{align*}
$$

The evaluation of $r_{P}$ and $r_{W}$ requires the evaluation of $C_{R}$ and $C_{D}$; quantities which are not experimentally available.

It may be postulated at this point that although $C_{R}$ and $C_{D}$ are never detectable, they $c$ an never be zero, or the reaction could not proceed. Since $C_{R}$ and $C_{D}$ are so low, the finjete rates of formation and disappearance of $R$ and $D$ respectively, must
be approximately identical and the net rate of formation of the intermediate compounds must tend toward zero, and thus may be taken as zero. This is a statement of the steady state hypothesis, i.e., the net rate of change in the concentration of an intermediate compound may be taken as zero.

The steady state approximation is applied as follows. The total rate of formation of components $R$ and $D$ is zero, but is also equal to:

$$
\begin{align*}
& 0=r_{R}=k_{3} C_{D} C_{B}-k_{4} C_{R} C_{W}-k_{5} C_{R}+k_{6} C_{P} C_{C}  \tag{9}\\
& 0=r_{D}=k_{1} C_{A} C_{C}-k_{2} C_{D}-k_{3} C_{D} C_{B}+k_{4} C_{R} C_{W} \tag{10}
\end{align*}
$$

Solving these expressions simultaneously for $C_{R}$ yields:

$$
\begin{equation*}
C_{R}=\frac{k_{1} k_{3} C_{A} C_{B} C_{C}+k_{2} k_{6} C_{P} C_{C}+k_{3} k_{6} C_{B} C_{P} C_{C}}{k_{2} k_{4} C_{W}+k_{2} k_{5}+k_{5} k_{3} C_{B}} \tag{11}
\end{equation*}
$$

Substituting Eq. (11) into Eq. (7) and simplifying yields:

$$
\begin{equation*}
r_{P}=\frac{k_{1} k_{3} k_{5} C_{A} C_{B} C_{C}-k_{2} k_{4} k_{6} C_{P} C_{W} C_{C}}{k_{2} k_{4} C_{W}+k_{2} k_{5}+k_{3} k_{5} C_{B}} \tag{12}
\end{equation*}
$$

Realizing that by initial conditions $\mathrm{k}_{3}$ and $k_{4}$ are very small as compared to $k_{1}, k_{2}, k_{5}$, or $k_{6}$, it may be said that the products of $k_{2}, k_{4}$, and
$C_{W}$, and $k_{3}, k_{5}$, and $C_{B}$ are negligible compared to the product of $k_{2}$ and $k_{5}$. The expression then reduces to:

$$
\begin{equation*}
r_{P}=\frac{k_{1} k_{3} k_{5} C_{A} C_{B} C_{C}-k_{2} k_{4} k_{6} C_{P} C_{W} C_{C}}{k_{2} k_{5}} \tag{13}
\end{equation*}
$$

By allowing:

$$
\begin{aligned}
& k_{\text {forward }}=k_{f}=\frac{k_{1} k_{3}}{k_{2}} \\
& k_{\text {backward }}=k_{b}=\frac{k_{4} k_{6}}{k_{5}}
\end{aligned}
$$

the kinetic rate expression for any esterification or hydrolysis reaction satisfying the $A_{A C}{ }^{2}$ mechanism may be written as:

$$
\begin{equation*}
r_{P}=k_{f} C_{A} C_{B} C_{C}-k_{b} C_{P} C_{W} C_{C} \tag{14}
\end{equation*}
$$

Finally, converting back to the original nomenclature:

$$
\begin{equation*}
r_{p}=k_{f}\left(R^{\prime}-\mathrm{CO}-\mathrm{OH}\right)(\mathrm{ROH})\left(\mathrm{H}^{+}\right)-\mathrm{k}_{\mathrm{b}}\left(\mathrm{R}^{\prime}-\mathrm{CO}-\mathrm{OR}\right)\left(\mathrm{H}_{2} \mathrm{O}\right)\left(\mathrm{H}^{+}\right) \tag{15}
\end{equation*}
$$

This rate expression may be made specific for any acid catalyzed esterification by substituting in the radicals used for $R$ and $R$ '.

## J. RATE OF CHEMICAL REACTION

The rate at which a chemical reaction proceeds, $-r_{A}$, expressed in terms of the number of molecules converted per unit time per unit volume depends on the frequency of collisions between the reacting molecules, and the fraction of these collisions occurring with sufficient energy to overcome the activation energy barrier. The fraction of collisions meeting this energy criterion $c a n$ be expressed by the Maxwell Distribution Law as a function of the absolute temperature, and is equal to $\exp (-E / R T)$.

Several other factors influence the effectiveness of these collisions. Among these are structural effects such as steric hindrance, which has been mentioned earlier, and energy-dissipation considerations. Factors such as these are essentially temperature independent, and may be combined in a temperatureindependent probability constant $P$. In addition, a frequency factor, $A$, may be defined as a measure of the frequency of the collisions of the reacting species. The frequency of collisions (which is inversely proportional to the mean free path of the molecules) increases as a function of temperature.

Therefore, it may be said that the rate of reaction is equal to the product of:

1. The frequency of the collisions between reacting species, which is a function of the concentration of the reacting species in the reaction mass.
2. The fraction of molecules colliding with sufficient energy to react.
3. The probability that these collisions will be fruitful in terms of orientation, quantum and energy-dissipation considerations.

The equation governing the reaction rate may be expressed as:

$$
\begin{equation*}
-r_{A}=P A \exp (-E / R T) \prod_{i=1}^{n}\left(C_{i}\right)^{\beta_{i}} \tag{16}
\end{equation*}
$$

The constant product, PA, is seen to be dependent upon temperature, but is generally treated as a temperature-independent constant $k_{0}$. This may be justified by the fact that the effect of temperature in the exponential term greatly outweighs its effect in the pre-exponential constant.

The rate expression may then be divided into three characteristic portions:

1. $k_{0}$, a constant with dimensions of (time) ${ }^{-1} \mathrm{x}$ (concentration) ${ }^{1-n}$, where $n$ is order of reaction.
2. $\exp (-E / R T)$ an exponential temperature function which is dimensionless, and
3. $\prod_{i=1}^{n}\left(C_{i}\right)^{\beta i}$, a concentration function explicit
in the concentration of each species present. $\mathcal{O}_{i}$ is the order of reaction with respect to the particular species.

The Arrhenius Equation

The non-concentration dependent functions in the rate expression described above can be stated by the Arrhenius equation.

$$
\begin{equation*}
k=k_{o} \exp (-E / R T) \tag{17}
\end{equation*}
$$

This equation describes the exponential increase in reaction rate constant with temperature, resulting from an increasing proportion of molecules possessing sufficient energy to overcome the activation energy barrier. Once the rate constants at two temperatures are known, the Arrhenius parameters may be calculated, enabling the calculation of the rate constant at any other temperature.

Other expressions have been developed to predict the temperature dependence of the reaction rate constant. The increased accuracy if any, obtained in using these relationships is far outweighed by the cumbersome calculational techniques and additional information required in their usage. The Arrhenius equation in general fits experimental data well over a wide range of temperatures, and
for most engineering applications is preferred because of its simplicity. For this reason, the Arrhenius equation was used throughout this work.

## K. EQUILIBRIUM CONSTANT

The equilibrium constant for a reversible reaction system may be mathematically derived in terms of the $A_{A C}{ }^{2}$ mechanism discussed earlier. The reactions occurring within the system may be written as:

$$
\begin{align*}
& \mathrm{A}+\mathrm{C} \underset{\mathrm{k}_{2}}{\stackrel{\mathrm{k}_{1}}{\rightleftarrows}} \mathrm{D}  \tag{4}\\
& \mathrm{~B}+\mathrm{D} \underset{\mathrm{k}_{4}}{\stackrel{\mathrm{k}_{3}}{\underset{~}{\rightleftarrows}} \mathrm{R}} \mathrm{R}+\mathrm{W}  \tag{5}\\
& \mathrm{R} \underset{\mathrm{k}_{6}}{\stackrel{\mathrm{k}_{5}}{\rightleftarrows}} \mathrm{D}+\mathrm{C} \tag{6}
\end{align*}
$$

It is assumed that each reversible reaction given is elementary in either direction.

Consider reaction (4). The rate equation for the forward reaction is:

$$
\begin{equation*}
-r_{A}=k_{1} C_{A} C_{C} \tag{18}
\end{equation*}
$$

and that for the reverse reaction is:

$$
\begin{equation*}
-\mathrm{r}_{\mathrm{A}}=-\mathrm{k}_{2} \mathrm{C}_{\mathrm{D}} \tag{19}
\end{equation*}
$$

The net rate of disappearance of reactant $A$ is the algebraic sum of the two reactions.

$$
\begin{equation*}
-r_{A}=k_{1} C_{A} C_{C}-k_{2} C_{D} \tag{20}
\end{equation*}
$$

When equilibrium is established, the net rate of disappearance of $A$ is zero,

$$
\begin{equation*}
-r_{A}=k C_{A e} C_{C e}-k_{2} C_{D e}=0 \tag{21}
\end{equation*}
$$

This equation describes the concept of dynamic equilibrium as the condition at which the rate of the forward reaction is identical to the rate of the reverse reaction, or

$$
\begin{equation*}
\mathrm{k}_{1} \mathrm{C}_{\mathrm{Ae}} \mathrm{C}_{\mathrm{Ce}}=\mathrm{k}_{2} \mathrm{C}_{\mathrm{De}} \tag{22}
\end{equation*}
$$

This equation may be rearranged to

$$
\begin{equation*}
\frac{\mathrm{k}_{1}}{\mathrm{k}_{2}}=\frac{\left(\mathrm{C}_{\mathrm{De}}\right)}{\left(\mathrm{C}_{\mathrm{Ae}} \mathrm{C}_{\mathrm{Ce}}\right)}=\mathrm{K}_{1} \tag{23}
\end{equation*}
$$

where $K_{1}$ is the equilibrium constant for this reaction.

The equilibrium expressions for $\mathrm{Eq}(5)$ and $\mathrm{Eq}(6)$ may be derived in a similar manner.

$$
\begin{align*}
& \frac{k_{3}}{k_{4}}=\frac{C_{R e} C_{W e}}{C_{B e} C_{D e}}=k_{2}  \tag{24}\\
& \frac{k_{5}}{k_{6}}=\frac{C_{P e} C_{C e}}{C_{R e}}=K_{3} \tag{25}
\end{align*}
$$

Solving $\mathrm{Eq}_{\mathrm{q}}(23)$ for $\mathrm{C}_{\mathrm{De}}$ and $\mathrm{Eq}_{\mathrm{q}}(25)$ for $\mathrm{C}_{\mathrm{Re}}$ and substituting the result in Eq(24) yields, with rearrangement

$$
\begin{equation*}
K_{1} K_{2} K_{3}=\frac{\left(C_{P e}\right)\left(C_{W e}\right)}{\left(C_{A e}\right)\left(C_{B e}\right)}=\frac{k_{1} k_{3} k_{5}}{k_{2} k_{4} k_{6}} \tag{26}
\end{equation*}
$$

Realizing that

$$
\begin{equation*}
k_{i}=k_{0 i} \exp \left(-E_{i} / R T\right) \tag{27}
\end{equation*}
$$

it may be written

$$
\begin{align*}
& \frac{k_{1} k_{3} k_{5}}{k_{2} k_{4} k_{6}}=\frac{k_{01} k_{03} k_{05} \exp }{k_{02}{ }_{0}{ }_{04} k_{06} \exp \left(-E_{1}-E_{3}-E_{5}\right) / R T}  \tag{28}\\
& \text { Defining the following quantities, } \\
& \left.k_{0 f}=\mathrm{E}_{4}-E_{6}\right) / R T  \tag{29}\\
& k_{01} k_{03} k_{05}  \tag{30}\\
& k_{0 b}=k_{02} k_{04} k_{06}  \tag{31}\\
& E_{f}=E_{1}+E_{3}+E_{5}  \tag{32}\\
& E_{b}=E_{2}+E_{4}+E_{6}
\end{align*}
$$

the final form of the equilibrium expression may be stated

$$
\begin{equation*}
K_{e q}=\frac{\left(C_{P e}\right)\left(C_{W e}\right)}{\left(C_{A e}\right)\left(C_{B e}\right)}=\frac{k_{O f} \exp \left(-E_{f} / R T\right)}{k_{O b} \exp \left(-E_{b} / R T\right)}=\frac{k_{f}}{k_{b}} \tag{33}
\end{equation*}
$$

The overall equilibrium constant for the reaction, Keq, is therefore defined.

The temperature dependency of the equilibrium constant is given by the van't Hoff equation,

$$
\begin{equation*}
\frac{\mathrm{d}\left(\ln \mathrm{~K}_{\mathrm{eq}}\right)}{\mathrm{dT}}=\frac{\Delta \mathrm{H}_{\mathrm{r}}}{\mathrm{RT}^{2}} \tag{34}
\end{equation*}
$$

where

$$
\begin{aligned}
\mathrm{T} & =\text { absolute temperature } \\
\mathrm{R} & =\text { universal gas constant } \\
\Delta \mathrm{H}_{\mathrm{r}} & =\text { heat of reaction }
\end{aligned}
$$

and

$$
\frac{d\left(\ln K_{e q}\right)}{d T}=\begin{aligned}
& \text { the rate of change of the } \\
& \text { equilibrium constant with } \\
& \text { respect to temperature. }
\end{aligned}
$$

As Kaplan (30) points out, most esterification reactions have negligibly small heats of reaction. In terms of the van't Hoff equation it may be said that the equilibrium constants for esterification reactions are functionally independent of temperature.

Glasstone (26) has indicated that the effect of catalyst on the equilibrium constant is negligible in all cases except those in which the catalyst affects the activities of the reactants. The effect of added hydrogen ions (in the form of mineral acid catalyst) on the equilibrium position of the reaction system in this study, may be examined in light of the derivation of the equilibrium constant consistent with the ${ }^{A} A^{2}$ mechanism. It $c$ an be seen by Eq (33), the final equilibrium expression in terms of the concentrations of the reacting compounds, that the equilibrium constant is independent of hydrogen ion concentration. In addition, lactic acid may be classified as a weak electrolyte and as such, the activity of this species may be satisfactorily expressed in terms of its concentration. On this basis,
the effect of catalyst on the equilibrium constant is assumed to be negligible in the present system.

## L. HOMOGENEOUS CATALYSIS

A homogeneous catalyst is defined as a nonstoichiometric quantity of an acid, base or specific ion that is miscible with the reactants and products, which has no effect on the stoichiometry of the reacting system, but results in an increase in the reaction rate. The phenomenon of homogeneous catalysis may be modelled as two reactions occurring in parallel, the catalyzed and uncatalyzed reactions.

Consider the following reaction scheme

$$
\begin{equation*}
A \longrightarrow R+S \tag{35}
\end{equation*}
$$

whose rate of reaction may be expressed as

$$
\begin{equation*}
-r_{A}=k_{1} C_{A} \tag{36}
\end{equation*}
$$

The catalytic reaction may be postulated as occurring by the following mechanism

$$
\begin{equation*}
\xrightarrow[{A C C \xrightarrow{A} \xrightarrow{\mathrm{k}_{4}} \mathrm{AC}}]{\mathrm{A}+\mathrm{S}+\mathrm{C}} \tag{37}
\end{equation*}
$$

Assuming that the first step of the above reaction is rate controlling, the rate of disappearance of reactant $A$ may be expressed as

$$
\begin{equation*}
-r_{A}=k_{2} C_{A} C_{C} \tag{39}
\end{equation*}
$$

The total rate of disappearance of $A$ is then

$$
\begin{equation*}
-r_{A}=k_{1} C_{A}+k_{2} C_{A} C_{C} \tag{40}
\end{equation*}
$$

or,

$$
\begin{equation*}
-r_{A}=\left(k_{1}+k_{2} C_{C}\right) C_{A} \tag{41}
\end{equation*}
$$

Since the catalyst is regenerated in the catalyzed reaction, its concentration remains essentially constant in the system, and the term $k_{2} C_{C}$ is therefore also constant. The observed overall rate constant for a homogeneously catalyzed reaction may then be given by

$$
\begin{equation*}
k_{o b s}=k_{1}+k_{2} C_{C} \tag{42}
\end{equation*}
$$

The observed constant, $k_{\text {obs }}$, will be constant for a given temperature and catalyst concentration, but it will vary linearly as a function of catalyst concentration.

It should be pointed out at this juncture that the foregoing technique does not rigorously apply to the lactic acid-butanol system. According to the $A C^{2}$ mechanism for esterification, the "uncatalyzed" reaction cannot proceed without the initial presence of some hydrogen ions. In the "uncatalyzed" system these ions would normally be supplied via dissociation of some carboxylic acid groups of the lactic acid. It is speculated that the addition of hydrogen ions by the catalyst would suppress the dissociation of the lactic acid yielding, at
extremely low catalyst concentrations, no net increase in hydrogen ion concentration. The effect would be offset as the catalyst concentration increases.

It is assumed for the purposes of this study that because lactic acid is a mild acid, with a dissociation constant of $1.374 \times 10^{-4} @ 25^{\circ} \mathrm{C}$, the approach presented above for correllation of the effect of catalyst concentration may be used with introduction of negligible error in the lower catalyst concentration ranges.

## M. REACTION SCHEME

Consistent with the reaction scheme proposed by Filachione and Fisher (25) for the reactions occurring in the esterification of lactic acid, the following expressions may be written:

$$
\begin{align*}
& M+B \underset{2}{\stackrel{1}{\rightleftarrows}} E_{1}+W  \tag{43}\\
& D+B \underset{4}{\rightleftarrows} E_{2}+W  \tag{44}\\
& E_{1}+M \underset{6}{\underset{~}{\leftrightarrows}} E_{2}+W \tag{45}
\end{align*}
$$

where,

$$
\begin{aligned}
& M=\text { monomeric lactic acid } \\
& \mathrm{CH}_{3} \mathrm{CHOHCOOH} \\
& \text { D = dimeric lactic acid } \\
& \mathrm{CH}_{3} \mathrm{CHOHCOOCH}\left(\mathrm{CH}_{3}\right) \mathrm{COOH} \\
& B=n \text {-butyl alcohol } \\
& \mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{OH} \\
& W=\text { water } \\
& \mathrm{H}_{2} \mathrm{O} \\
& \mathrm{E}_{1}=\text { buty11actate } \\
& \mathrm{CH}_{3} \mathrm{CHOHCOOC} 4{ }_{4}{ }_{9} \\
& E_{2}=\text { butyllactyllactate } \\
& \mathrm{CH}_{3} \mathrm{CHOHCOOCH}\left(\mathrm{CH}_{3}\right) \mathrm{COOC}_{4} \mathrm{H}_{9}
\end{aligned}
$$

In water solutions of lactic acid ranging up to $85 \%$, an equilibrium exists between monomeric (M) and dimeric (D) acid. It has been shown by Watson (62) that the higher weight polylactic acids are not present.

Assuming the added inhibition of steric hindrance in the esterification of butyllactyllactate, the probability of higher chain length esters is very small. It is therefore assumed that no further reactions are occurring in this system.

In the case of the self-esterification of monomeric lactic acid, it has been shown by Kaplan (30), and confirmed in this investigation that the reaction is extremely slow, even in the presence of a catalyst at elevated temperatures, (Appendix A). It is therefore assumed that the effects of this reaction are unimportant and it therefore need not be considered.

## N. REACTOR DESIGN EQUATIONS

The major equipment used throughout this kinetic study was a constant flow stirred tank reactor, commonly called a backmix or total backmix reactor. This reactor system offers the advantage of simplicity in operation combined with relatively easy interpretation of results. In the ideal steady-state backmix reactor the contents are well stirred and the composition of the reaction mass is homogeneous throughout the system. The effluent stream from this reactor has the same composition as the fluid within the reactor. The reactor design equation for a constant flow stirred tank reactor may be derived using the techniques presented in Levenspiel (28).

The starting point for all design is the general material balance expressed for any reaction component. Such a material balance for any reactant may be expressed for any bound system in the following form:

$$
\begin{gather*}
\binom{\text { rate of reactant }}{\text { flow into system }}=\binom{\text { rate of reactant flow }}{\text { out of system }}+\ldots \\
\cdots\left(\begin{array}{l}
\text { rate of reactant } \\
\text { loss due to chemical } \\
\text { reaction within system }
\end{array}\right)+\left(\begin{array}{l}
\text { rat accumulation } \\
\text { of reactant within } \\
\text { system }
\end{array}\right) \tag{46}
\end{gather*}
$$

In the present case, the system is the reaction
mass and the boundary is the wall of the reactor.

Assuming only the steady-state case, the rate of accumulation of reactant within the system is zero, and the material balance reduces to:

$$
\begin{equation*}
\binom{\text { rate of reactant }}{\text { flow into system }}=\binom{\text { rate of reactant }}{\text { flow out of system }}+\ldots \tag{47}
\end{equation*}
$$

Since the composition is uniform throughout, the balance may be applied about the reactor as a whole. Expressing the molar feed rate of component A into the reactor in terms of the volumetric feed rate, and the concentration of component $A$ in the feed,

$$
\begin{equation*}
F_{A i}=v_{i} C_{A i} \tag{48}
\end{equation*}
$$

where

$$
\begin{aligned}
& \mathrm{F}_{\mathrm{Ai}}=\text { molar feed rate, moles/time } \\
& \mathrm{v}_{\mathrm{i}}=\text { volumetric feed rate, volume/time } \\
& \mathrm{C}_{\mathrm{Ai}}=\text { concentration of } A \text { in feed, moles A/unit } \\
& \text { volume }
\end{aligned}
$$

The following rates $c$ an be written
Input of $A$, moles/time $=F_{A i}=F_{A i}\left(1-X_{A i}\right)$
Output of $A$, moles/time $=F_{A f}=F_{A i}\left(1-X_{A f}\right)$

Disappearance of A by reaction, moles/time $=$

$$
\begin{align*}
\left(-r_{A}\right)_{\mathrm{f}} \mathrm{~V}= & \left(\begin{array}{l}
\text { moles of A reacting } \\
\text { (time) (volume of react }- \\
\text { ing fluid) }
\end{array}\right)  \tag{51}\\
& \left(\begin{array}{l}
\text { volume of reactor } \\
\text { occupied by reacting } \\
\text { fluid }
\end{array}\right)
\end{align*}
$$

where

$$
\begin{aligned}
& X_{A i}=\text { initial conversion of reactant } A \\
& X_{A f}=\text { final conversion of reactant } A \\
& \left(-r_{A}\right)_{f}=\text { rate of disappearance of component } A
\end{aligned}
$$ at existing reactor conditions, (moles)/(unit volume) (time)

$\mathrm{V}=$ volume of reacting fluid.
Substituting equations (49), (50) and (51) into
equation (47) yields

$$
\begin{equation*}
F_{A i}\left(1-X_{A i}\right)=F_{A i}\left(1-X_{A f}\right)+\left(-r_{A}\right)_{f} V \tag{52}
\end{equation*}
$$

or, with simplification,

$$
\begin{equation*}
F_{A i}\left(X_{A f}-X_{A i}\right)=\left(-r_{A}\right)_{f} V \tag{53}
\end{equation*}
$$

Rearrangement gives

$$
\begin{equation*}
\frac{v}{F_{A i}}=\frac{V}{v_{i} C_{A i}}=\frac{X_{A f}-X_{A i}}{\left(-r_{A}\right)_{f}} \tag{54}
\end{equation*}
$$

In the subject system, the reactants are not contacted until they enter the reactor. Therefore, the initial conversion, $X_{A i}=0$. Then,

$$
\begin{equation*}
\frac{V}{v_{i}}=\frac{C_{A i} X_{A f}}{\left(-r_{A}\right)_{f}} \tag{55}
\end{equation*}
$$

Finally, the quantity space time, $\boldsymbol{\tau}$, having units of time, may be defined as the time required to process one reactor volume of feed measured at specified conditions. The space time may be expressed as:

$$
\begin{gather*}
\tau=\frac{V}{v_{i}} \\
(\text { reactor volume) } /(\text { volumetric feed rate }) \tag{56}
\end{gather*}
$$

Combining equation (55) and (56) yields the final working form of the design equation for the backmix reactor.

$$
\begin{equation*}
\tau=\frac{V}{v_{i}}=\frac{V_{A i}}{F_{A i}}=\frac{C_{A i} X_{A f}}{\left(-r_{A}\right)_{f}} \tag{57}
\end{equation*}
$$

Knowing the reactor volume, volumetric feed rates, and reactor effluent concentrations, permits the calculation of the observed rate constants of the reactions occurring within the system.

## 0. PRIOR LACTIC ACID KINETIC INVESTIGATIONS

In previous sections of this report, the long and varied history of lactic acid has been discussed. In spite of lactic acid's early discovery and the extensive commercial exploitation of this versatile acid, basic studies into the kinetics of this system have been few. To date only four investigations have appeared dealing with the kinetics of esterification of lactic acid.

Three of the investigations appearing in the 1iterature, those of Troupe and Kobe (56), Troupe and Kobe (57), and Troupe and Dimilla (55), are similar in their approach to the determination of the rate constant and will therefore be discussed together. Troupe and Kobe studied the esterification of lactic acid with methanol in the presence of sulfuric acid catalyst. Troupe and Dimilla investigated the kinetics of the ethanol-lactic acid reaction catalyzed by sulfuric acid.

Two grades of lactic acid were used in these studies; reagent grade, $85 \%$ lactic acid, and $44 \%$ technical grade lactic acid. In total, four systems were studied; each alcohol with each of the acid concentrations given above.

Before presenting the results of these investigations it is pertinent to discuss the assumptions made by the investigators in the analysis of their findings.

The only reactions assumed to be occurring within the system were:

1. The Esterification of Monomeric Acid

$$
\begin{equation*}
\mathrm{CH}_{3} \mathrm{CHOHCOOH}+\mathrm{CH}_{3} \mathrm{OH} \longrightarrow \mathrm{CH}_{3} \mathrm{CHOHCOOCH}_{3}+\mathrm{H}_{2} \mathrm{O} \tag{58}
\end{equation*}
$$

and,
2. The Hydrolysis of Lactic Acid Condensation Polymers

HO $\left(\mathrm{CH}\left(\mathrm{CH}_{3}\right) \mathrm{COO}\right)_{\mathrm{n}}{ }^{\mathrm{H}}+(\mathrm{n}-\mathrm{I}) \mathrm{H}_{2} \mathrm{O} \longrightarrow \mathrm{n}\left(\mathrm{CH}_{3} \mathrm{CHOHCOOH}\right)$
The irvestigators were aware of the presence of lactyllactic acid in thetr reaction gystem but chose to neglect eny renction of alcohol with this component. Further esterification of the esters was not considered.

In addition, the correlation of the kinetic rate data was done entirely on an empirical basis. No reaction mechanisms were postulated nor were any rate expressions derived. The general kinetic relationship arrived at in all three investigations was of the form:

$$
\begin{equation*}
k t=\frac{x}{(A-b)(A-b-x)} \tag{60}
\end{equation*}
$$

where:
$A=$ total lactic acid originally present, moles
$b=a f u n c t i o n ~ o f ~ t h e ~ r e a c t a n t ~ r a t i o, ~ m o l e s ~$
$x=$ the amount of lactic acid converted in time $=t$, moles
$t=r e a c t i o n ~ t i m e, ~ m i n u t e s$
$k=$ specific reaction rate constant, liter/mole-minute

The functional relationships between the rate constant and the reaction temperature, catalyst concentration and mole ratio of reactants were also determined.

The final forms of the four correlations are given below. In all the forms presented, the following consistent nomenclature is used.
$(A / L)=$ mole ratio of alcohol to acid
C $\quad=$ weight percent sulfuric acid catalyst
$\mathrm{T}=$ temperature, ${ }^{\circ} \mathrm{K}$

Methanol-85\% Lactic Acid (Reagent Grade)

$$
\begin{align*}
& k=(0.08750(A / L) C-0.08955 C+0.00435) \\
&\left(\frac{10(10.91369-3139.3 / T)}{314.3}\right) \tag{61}
\end{align*}
$$

## Methanol-44\% Lactic Acid (Technical Grade)

For catalyst concentrations up to $0.417 \%$ sulfuric acid,
$\mathrm{k}=(0.0001755(\mathrm{~A} / \mathrm{L})+0.0005807)\left(\frac{10^{(10.36400-3069.3 / T)}}{136.5}\right)$
For catalyst concentrations above $0.417 \%$ sulfuric acid,

$$
\begin{gather*}
\mathrm{k}=(0.000422(\mathrm{~A} / \mathrm{L})(\mathrm{C})+0.014175 \mathrm{C}-0.005334) \\
\left(\frac{10(10.36400-3069.3 / \mathrm{T})}{136.5}\right) \tag{63}
\end{gather*}
$$

Ethanol - $85 \%$ Lactic Acid (Reagent Grade)

$$
\begin{gather*}
k=(0.03120(A / L) C-0.0150 C+0.001895) \\
\left(\frac{10(11.086-3265 / T)}{215.1}\right) \tag{64}
\end{gather*}
$$

Ethanol - 44\% Lactic Acid (Technical Grade)
For catalyst concentrations up to $0.263 \%$ sulfuric acid,
$\mathrm{k}(0.0001031(\mathrm{~A} / \mathrm{L})+0.00024)\left(\frac{10^{(8.721-2579 / \mathrm{T})}}{64.1}\right)$
For catalyst concentrations above $0.263 \%$ sulfuric acid,

$$
\begin{gather*}
k=(0.000342(\mathrm{~A} / \mathrm{L}) \mathrm{C}+0.00177 \mathrm{C}-0.000218)  \tag{x}\\
\left(\frac{10(8.721-2579 / \mathrm{T})}{64.1}\right) \tag{66}
\end{gather*}
$$

The level response of rate constant to catalyst concentration for technical grade lactic acid in the low catalyst ranges is explained by the authors as the result of reaction of the catalyst with impurities in the acid.

An interesting effect is noted when the predicted rate constants at the two acid concentrations with either alcohol are compared. (Table III). The predicted constants for $88 \%$ lactic acid are 20 to 30 times those for $44 \%$ acid. Theory predicts that the rate constant for a reaction should be independent of the reactant concentration. It is felt by this author that the deviation of these results from theory is a result of the neglect of certain reactions occurring in the system. These are namely, the esterification of lactyllactic acid and the esterification of the alcoholic esters of lactate with lactic acid.

Kaplan (30) investigated the kinetic data of the somewhat "synthetic" system of monomeric lactic acid and normal butyl alcohol. The variables

## TABLE III

Predicted Rate Constants For Different Lactic
Acid Solutions (55, 56, 57)

| Temperature |  | $350^{\circ} \mathrm{K}$ |
| :---: | :---: | :---: |
| Catalyst Concentration, Weight Per Cent |  | 0.10 |
| Mole Ratio of Alcohol To Acid |  | 5.00 |
| Alcohol | Predicted Rate Consta 1iter/mole-min |  |
| Lactic Acid Concentration | 85\% | 44\% |
| Methanol | 0.01093 | 0.000365 |
| Ethanol | 0.00424 | 0.000264 |

studied were reaction temperature and catalyst concentration. Only one reaction was assumed to occur within the system, the reaction between monomer and alcohol:

$$
\mathrm{CH}_{3} \mathrm{CHOHCOOH}+\mathrm{C}_{4} \mathrm{H}_{9} \mathrm{OH} \rightleftarrows \mathrm{CH}_{3} \mathrm{CHOHCOOC} 4{ }_{4} \mathrm{H}_{9}+\mathrm{H}_{2} \mathrm{O}
$$

The data were correlated as a second order reversible reaction, and the Arrhenius parameters were determined for the system. For the uncatalyzed system the activation energy was found to be 13,190 calories and the pre-exponential constant was 673 liter/mole-second. The activation energy for the catalyzed reaction was found to be 13,580 calories with a frequency factor of 547 liters ${ }^{2} /$ mole-secondmmole catalyst. The equilibrium constant for the esterification reaction found was 3.02 .

A further discussion of Kaplan's work is warranted at this point. As mentioned, the system studied by Kaplan was "synthetic". That is, concentrated solutions of lactic acid with dimer concentrations of approximately $4.5-9 \%$ do not occur naturally. The utility of kinetic data derived from this is therefore quite limited in an application such as the industrial design suggested.

In addition, Kaplan, as did the investigations of T'roupe, neglected the possibility of reaction between dimer and alcohol. The experimental design used by Kaplan was intended to reduce the importance of the dimer esterification by reducing the concentration of dimer in the reaction mass. However, the dimer concentration in his initial lactic acid mixture was as high as $9 \%$ by weight, with a corresponding monomer concentration of $71 \%$. In terms of reacting species, the percentage of total carboxylic acid groups in the reaction mass attributable to dimer ranged from 3.5 to $6.5 \%$. At equilibrium, the dimer carboxylic acid groups represent $24.2 \%$ of the total. On this basis, it is felt that the assumption of negligible dimer esterification is invalid.

The experimental results presented in this work differ from prior investigations in one major respect. All possible reactions occurring in the system have been included. As mentioned previously, the works of Troupe ( $5 \underline{6}, \underline{57}, \underline{58}$ ) approached the study of the kinetics of lactic acid-alcohol reactions from a completely empirical viewpoint. No mechanistic assumptions were made. In addition, Troupe chose to neglect the possible reactions of other acid and
alcoholic constituents within the reaction system.

Kaplan attempted to reduce the importance of the dimer-alcohol reaction by reducing the concentration of dimer to negligible proportions. As explained above, he was not successful, and his correlations were in error in this respect.

The current work has approached the lactic acidalcohol kinetic study from a theoretical direction and has made only justifiable assumptions regarding the mechanisms of the reaction scheme.

## CHAPTER II

## Experimental Procedures

## A. RAW MATERIALS

## Lactic Acid

The lactic acid used in this experiment was purchased from the Clinton Corn Processing Company. Clinton lactic acids are made with the use of special strains of the lactic acid-producing bacteria, (lactobacillus), which produce the acid by their action on various grades of dextrose. The resulting dilute acid solutions are refined to meet the specifications of the different grades of lactic acid and concentrated (by the evaporation of water), to the percent acid required.

Two Clinton lactic acid products are available for industrial use: Light Technical Grade Lactic Acid and Dark Technical Grade Lactic Acid. The differences between them are primarily attributed to the refining each receives. The light Technical may be considered to be intermediate between the Food Processing and Dark Technical Grades. The Light is of higher purity than the Dark, having a lighter color and containing smaller percentages
of protein, carbohydrates and metal salts.

The grade of lactic acid used throughout this work was the Light Technical Grade, 80 percent acid. The acid was used as it came from the drum, with no further purification or modification of composition. Acid analyses were performed periodically throughout the course of this investigation and the composition ras found to be ossentially constant.

Acid composition was analyzed by the method of Eder and Kutter (19), which was modified (see page 76) to fit the equipment of this investigator. The analysis of the lactic acid solution, based on several sets of replicate samples is presented in Table IV. The Table also gives the 95 percent confidence range of the component concentrations.
n-Butyl Alcohol
Technical grade n-butyl alcohol purchased from Commercial Solvents Corporation was uscd as the alcoholic component of the esterification reaction. Commercial Solvents butanol is sold as $99 \%$ pure. (Chromatographic analysis of the butanol showed only one peak, indicating no detectable impurities). The alcohol was used straight from the drum with no further purification.

## TABLE IV

## Butyl Lactate

Reagent grade butyl lactate from the Baker Chemical Company was used as a chromatographic standard. Water content of the butyl lactate by Fisher water assay was less than 0.20 per cent. Chromatographic analysis of the butyl lactate showed the presence of no major impurities.

Hydrochloric Acid

Reagent grade hydrochloric acid, obtained from the Baker Chemical Company, was used as the acid catalyst in this investigation. The hydrochloric acid is sold as a 37 per cent aqueous solution.

## B. ANALYTICAL TECHNIQUES

## Titration Techniques

The technique used to determine the total acid and total ester content of a sample was a modification of the method of Eder and Kutter (19). Simply stated, the method involved the titration of total acid groups present using a standard base, addition of excess base with subsequent saponification of the ester groups, and back titration of the remaining base with standard acid to determine the amount of base consumed in saponification. The method routinely followed in all total acid and total ester analyses is as follows:

1. An aliquot sample, P grams, (approximately $0.8 c c$ ) was weighed by difference, via a $1.0 c c$ syringe, into a 250 ml beaker.
2. The sample was diluted to approximately 100 cc with distilled water.
3. This solution was titrated to pH 7.0 with $0.1 \mathrm{~N} \mathrm{NaOH},(A \mathrm{mls})$, using a Beckman automatic titrator.
4. Sufficient excess of 0.1 N NaOH was added to saponify all ester groups present. (B mls) generally, 20 cc of excess base was enough. 5. Saponification was speeded by heating
the sample in $a$ hot water bath for 3 hours at $90^{\circ} \mathrm{C}$.
5. The solution was cooled to room temperature and backtitrated to pH 7.0 with a standard 0.05 N HC1 solution, ( C mls ).

At this point, the modification of the technique of Eder and Kutter (19), made by this author should be explained. The suggested technique involved the saponification of the ester in a steam bath at $100^{\circ} \mathrm{C}$ for 15 minutes. Since a hot water bath at $90^{\circ} \mathrm{C}$ was used in this work, it was found that 15 minutes was not sufficient to saponify all ester present. A minimum of 2 hours in the bath was required to obtain reproducible results. To be certain all ester reacted, a time of 3 hours at $90^{\circ} \mathrm{C}$ was taken as standard.

The analysis of the experimental data taken by the above technique varied slightly depending on whether the sample was feed lactic acid or reactor product. The calculational approach used in each case is outlined below.

Calculation of lactic acid composition was performed as follows. By knowledge of the components present, it is realized that each monomer molecule
contains one acid group. It is also known that each dimer molecule contains one acid group and one ester group. Therefore, the total ester present in the feed sample is equal to the total amount of dimer. The difference between the amount of dimer and the total acid present is the amount of monomer. In equation form this is written as:

$$
\begin{array}{r}
\text { Total acid }=(A, \text { ml NaOH }) \times(X, \text { mmoles } / \mathrm{ml} \mathrm{NaOH}) \\
= \tag{67}
\end{array}
$$

Total ester $=(B, m 1 \mathrm{NaOH}) \times(X, m m o l e s / m l ~ N a O H)-$ (C, ml HC1) x (Y, mmoles/m1 HC1) $=$ mmoles base reacting with ester = mmoles ester

Where $X$ and $Y$ are the molarities of the standard base and acid respectively. Then,

$$
\begin{align*}
\text { mmoles ester } & =\text { mmoles dimer }  \tag{69}\\
\text { mmoles acid }- & \text { mmoles ester }=\text { mmoles } \\
& \text { monomer } \tag{70}
\end{align*}
$$

The mmoles of acid and ester per gram are obtained by dividing through by the sample weight. Thus,

$$
\begin{equation*}
\text { mmoles dimer/gram }=\frac{B X-C Y}{p} \tag{71}
\end{equation*}
$$

mmoles monomer/gram $=\frac{A X-B X+C Y}{P}$

Weights may be obtained by multiplying through by the proper molecular weight. Water content is obtained by difference.

Calculation of reaction products was basically the same as the approach given above, except that since the relative amounts of ester groups attributable to dimer, butyl lactate or butyllactyllactate are unknown, the calculation $c a n$ not proceed past equation (68). That is,

$$
\begin{align*}
& \text { Total Acid }=A X / P, \quad \text { mmoles/gram }  \tag{73}\\
& \text { Total Ester }=B X-C Y / P, \quad \text { mmoles/gram } \tag{74}
\end{align*}
$$

## Catalyst Determination

Catalyst was added to the reaction mass via the $n$-butanol feed stream. Varying amounts of HC1 catalyst were injected into the butanol feed flask immediately prior to the start of a run. Catalyst was analyzed for by titration of the feed butanolcatalyst mixture to pH 7.0 immediately after the termination of the run. Since the moles of catalyst per gram of butanol were known, and the grams of butanol per gram of reaction mass were
known from the feed rates, the moles of catalyst per gram of reaction mixture could be calculated.

## Automatic Titrator

All acid-base titrations were performed using a Beckman Model K Automatic Titrator. The Model K Titrator, consisting of one control unit and two delivery units (one each for acid and base), provided a convenient, rapid means of conducting the titrations. Titrating accuracy of up to 0.1 per cent can be expected from this unit. The end point of the titrations was established by standardization with buffer solution of pH 7.0. The unit was standardized prior to the analysis of a particular run. Standard glass and calomel electrodes were used as the electrode pairs on the titrator.

## Chromatographic Techniques

The determinations of the butanol and butyl lactate components of the reaction mass were performed by chromatographic techniques. The chromatograph used in this study was a dual column, $F$ and $M$ model 810 flame ionization gas chromatograph. The column was 8 feet long by $1 / 8$ inch diameter, packed with 10 per cent phosphoric acid on Diatoport S 80-100 substrate. The standard operating conditions on
the chromatographic unit were:

| gas flow rate | 2.5 scale reading |
| :--- | :--- |
| helium pressure | 56.0 psi |
| hydrogen pressure | 26.0 psi |
| oxygen pressure |  |
| detector temperature | 40.0 psi |
| injection block <br> temperature | $210^{\circ} \mathrm{C}$ |
| oven temperature |  |
| (isothermal) |  |
| attenuation |  |

These conditions gave excellent separation of the butanol and butyl lactate peaks.

Calibration of the unit was done via an internal standard incorporated with the sample of the reaction product. The technique used is as follows. Prior to each day's run, a chromatographic standard was carefully weighed; it consisted of drum butanol, butyl lactate, and diphenyl ether. Diphenyl ether was selected as the standard material on the basis of its miscibility with the reaction mixture, its inertness with respect to the components of the reaction mixture, and its relatively high boiling point. The diphenyl ether peak came out of the chromatograph several minutes after the butanol and butyl lactate peaks.

Several injections of the standard were made to determine the calibration in terms of the butyl lactate to diphenyl ether and the butanol to diphenyl ether area ratios. The premise in this calibration technique was that the butanol, butyl lactate, and diphenyl ether peak areas are related to the relative quantity of that material present. In addition, the response of the area-to-weight ratio of one component relative to another are proportional. The technique is commonly used in quantitative chromatographic analysis. The relationship may be summed up as

$$
\begin{equation*}
\frac{(\text { Area } A / w t . A)_{1}}{(\text { Area } B / w t . B)_{1}}=\frac{(\text { Area } A / w t . A)_{2}}{(\text { Area } B / w t . B)_{2}}=\text { constant } \tag{75}
\end{equation*}
$$

From this standard, the constant may be evaluated.

The sample analysis proceeded as follows. A sample of reaction product was weighed by difference into a known weight of diphenyl ether. Generally 4.0 to 4.5 grams of sample to 0.5 grams of ether was used. This mixture was then immediately injected into the chromatograph and the response peaks obtained. The samples were cooled prior to mixing but not cooled after mixing. For this reason, the samples were never allowed to age more than 20 minutes to decrease the chance of additional reaction. Three injections were made of each sample.

Data for a typical analysis is given in Table V.

All chromatographic peak areas were determined by means of a Gelman Model 39231 Compensating Polar Planimeter. Each peak was transversed four times to determine an average value of the area.

It should be mentioned at this point that the constants evaluated from the standard were reproducible within the day but varied from day to day. The butanol constant varied from 0.929 to 1.075. The butyl lactate constant varied from 0.503 to 0.620 . This is most probably due to the result of the slight uncertainty in resetting the conditions of the chromatograph. Resetting was necessitated by the fact that the same chromatograph was being used simultaneously by other investigators.

## C. DESCRIPTION OF ESTERIFICATION EQUIPMENT

Figure 2 is a schematic drawing of the continuous esterification apparatus used throughout this investigation. Feed reservoirs consisted of two 4-1 Erlenmeyer flasks; one each for the butanolcatalyst mixture and the 80 per cent lactic acid solution. The reactants were pumped from their respective feed flasks to the reaction vessel by means of a DCL Series II Micropump. The pump heads (both 非3 DCL) were driven from the same shaft, with the volumetric flow rates delivered being controlled by a micrometer dial adjustment of piston stroke. Throughout the series of runs performed, micrometer settings of 5.0 were maintained on both pump heads. Al1 lines connecting equipment pieces were either glass or tygon. The lines between the pump heads and the reactor were tygon, and these lines were elevated above the level of the liquid in the reactor to trap any air bubbles entering the system and to reduce any possible back flow of reaction mass from the vessel into the pumping lines. Periodic checking of pumping rates showed them to be reproducible with approximately one per cent error.

The 670 ml overflow backmix reactor was equipped with an outer jacket to permit the circulation of a

Figure 2
SCHEMATIC OF EXPERIMENTAL EQUIPMENT CONFIGURATION
heating medium which consisted of $80 \%$ glycerin and $20 \%$ water. The reaction volume was completely surrounded by the heating medium. The reactor also contained four baffles to retard any vortex formation and thereby produce better mixing. The reactor contained the following openings: 1. Two connections at the base of the reactor for feed entrance. 2. One overflow connection at the top of the reactor for product exit. 3. Two jacket connections for heating medium circulation. 4. One jointed opening at the top for entrance of agitator shaft. 5. One jointed thermometer opening. 6. One stopcock at the base of the reactor for draining and/or sampling.

Mixing was accomplished using a Bodine Electric Company 36:1 Speed Reducer Motor Type NSE11R whose speed of rotation was controlled by means of a Variac. The speed was kept constant throughout the series of experiments at 2050 rpm . This motor drove a teflon paddle at the end of a glass stirring rod. The paddle height was adjusted below the center of the reactor, near the entrance reactant streams, to insure rapid and complete mixing.

Verification of thorough mixing in the reactor
was made by variation of stirrer speed and product sampling point. Samples were taken at 80 to 100 per cent of maximum speed. These samples were taken from the bottom drain stopcock and immediately after the overflow connection. Titration of these samples indicated only statistical variation in the total acid obtained. To insure maximum effectiveness, the stirrer was run at maximum speed throughout all runs. Sampling was done after the overflow connection to eliminate the possibility of reactant "short circuiting" the reactor.

A thermometer entering through the other jointed neck of the reactor provided the temperature readout. The accuracy of the thermometer was $\pm 0.2^{\circ} \mathrm{C}$. It was determined in the course of running that the temperature of the reactor varied $\pm 0.3^{\circ} \mathrm{C}$, varying with the temperature of the heating medium reserve tank.

The product exited through the overflow connection. The exit line was vented by means of a "Y" tubing connection. This vent served to prevent vacuum locking and thus eliminated siphoning of product from the reactor. The overflow led to a water-cooled Allihn condenser to cool the product stream and thereby decrease the amount
of butanol vapors in the room. The product finally dripped into a five gallon waste bottle.

Sampling was done via a three way stopcock in the exit line, located immediately after the overflow port of the reactor. The samples were cooled during the sampling by passage through a condenser. This served to prevent the escape of butanol and water vapors, thereby giving a true sample of the reactor product.

## D. RUN PROCEDURE

Immediately prior to the start of a run, the lactic acid feed supply flask was flushed with fresh lactic acid and filled; the butanol feed flask was flushed with butanol to remove residual butanolcatalyst mixture and filled with butanol. An approximate volume of HCl catalyst was added to the butanol by means of a 20 cc syringe. The hydrochloric acid volume was not carefully measured because exact catalyst determination was subsequently performed on the mixture. The butanol-catalyst mixture was thoroughly stirred to insure complete mixing.

The pumps were turned on and the reactor began to fill. The heater was turned on, set approximately ten degrees above the reactor temperature. This setting was later adjusted to yield the desired temperature. When the reactor was about one third full, the stirrer was begun at a low speed so as to avoid the mixing of air with the reactants. As the reactor filled, the rate of stirring was increased. When the reactor began to overflow, the stirrer was set at the proper speed, and the water flow through the condenser was begun. After running for three hours, (approximately six reactor volumes), the sampling stopcock was flushed and several samples
were taken at once in 5 ml test tubes. To verify the attainment of steady-state, earlier runs were sampled at two and one-half hours and three hours after the reactor began to overflow (sample separation about one reactor volume). No detectable difference was noted between total acid and total ester results at the two times. The system was therefore considered to be at steady state after three hours on all subsequent runs. Product samples were sealed and immediately immersed in a dry-ice-acetone bath; remaining there until immediately prior to analysis.

## E. SAMPLE EXPERIMENTAL RUN

A11 runs were performed using the previously outlined experimental procedures. The outline of a typical experimental run and the presentation of the raw data taken from this run will be presented in this section. The presentation of this sample experimental run will be helpful in visualizing how all the experimental data in this investigation was obtained.

Run No. 107 was performed within a series of runs at a reactor temperature of $60.0^{\circ} \mathrm{C}$. Circulation bath temperature was therefore initially set. Pumping rates were held constant at a vernier setting of 5.0 on both heads. These settings were not changed throughout all experimental runs. Subsequent to the experimental runs, two verification runs were made at varying alcohol/acid feed ratios. These runs are discussed in Chapter III.

Immediately prior to the initiation of the run, 37 cc of HCl catalyst were injected into approximately 2.51 of butanol contained in the butanol feed flask. After the mixture was thoroughly stirred, pumping was started. Three hours after the reactor had begun to overflow, four 5 ml samples were
taken by the afore-mentioned procedure. Customarily, two of these four samples were analyzed. The remaining two were taken as back-up samples in the event of a mishap. The samples were removed from the ice bath just before analysis and allowed to thaw to the point where the sample would flow.

Prior to the start of product analysis, samples of the butanol-catalyst mixture were taken. These samples were weighed by difference into 250 ml beakers and titrated to pH 7.0. The results of these titrations are given in Table VI. The acid concentration in the feed butanol mixture, in units of mmoles per gram of mix, are known directly by this titration. The final catalyst concentration in the product mixture may be calculated from the mmoles per gram of mixture and the weight ratio of grams of butanol per gram of total feed.

Product titration samples were weighed by difference, via a syringe, into 250 ml beakers. Initially, four titration samples were prepared. This number was later cut to three when it was found that titration analysis was very reproducible. The samples were diluted one at a time with approximately 100 cc of distilled water and titrated to pH 7.0. The results of these titrations are given
in Table VI. Elapsed time from the initiation of weighing to the final acid titration was approximately 10 minutes.

When initial acid titrations were completed, excess base was added to each sample, the samples were saponificed for 3 hours at $90^{\circ} \mathrm{C}$, cooled to room temperature and back-titrated with standard acid. These results are also resented in Table VI.

Chromatographic samples were prepared by first difference weighing the diphenyl ether into 20 ml jointed erlenmeyer flasks. The product sample was removed from the ice bath, thawed, and weighed by difference into the diphenyl ether. The sample was thoroughly mixed, and chromatographic injections begun. Elapsed time from the initiation of weighing until the completion of chromatographic injection was approrimately 20 minutes. The results of theso analyses are given in Table VI.

Total acid (corrected for catalyst), total ester, weight fraction butanol and weight fraction butyl lactate may be obtained directly from this data.

## CHAPTER III

## EXPERIMENTAL RESULTS

The esterification of an aqueous 80 percent lactic acid solution with $n-b u t a n o l$ was studied at three temperature levels and varying catalyst levels. The catalyst levels determined ranged from zero to 45 mmoles/liter. Reaction was performed in an overflow backmix reactor with volumetric input rate maintained constant. Reactor residence time varied slightly with the reaction temperature and the composition of the product stream. Experimental residence times varied from 1315 sec at $60^{\circ} \mathrm{C}$ to 1244 sec at $80^{\circ} \mathrm{C}$.

The data taken for a typical run are presented in Table VI. A tabulation of total acid, (corrected for catalyst), total ester, butanol, butyl lactate and catalyst data are presented in Appendix B. Mean values of total acid, total ester, butanol, and butyl lactate are plotted versus catalyst concentration in Figures 3, 4, 5, and 6.

To smooth the raw experimental data and to simplify further calculations, all experimental data at the three temperature levels were correlated by curvilinear regression using least squares poly-

nomials. Excellent fit to all data was obtained with second order polynomial equations in terms of catalyst concentration. The resultant polynomials are presented in Table VII, and shown in Figures 3, 4, 5, and 6. Table VII also presents the index of determination of the correlation, (a measure of the probability that this data can be represented as a second degree polynomial), and the standard error of the estimate for the dependent variable. As can be seen from this table, correlation was quite good.

Summary computer printouts for all experiments, showing the actual data, predicted data and the percent difference between the two are given in Appendix $C$.

## Material Balances

Consistent with the possible reaction models proposed earlier and with the knowledge of initial feed compositions, material balances may be written to determine the amounts of the various components within the reaction mass.

It is known from the reaction stoichiometry that the total acid (corrected for catalyst content), must be equal to the acid groups attributable to the

Table VII, Cont'd.

| ${ }^{\text {Temp }}{ }^{\circ} \mathrm{C}$ |  | Least Squares Equation* | Index of Determ | Std Error of Est for Y |

|  |  | Butyl Lactate |  |  |
| 60 |  | $0.157258+11.9354 C-68.5898 \mathrm{C}^{2}$ | 0.9869 | 0.014991 |
| 70 | $\mathrm{Y}_{4}$ | $0.382067+11.3141 C-53.2379 \mathrm{C}^{2}$ | 0.9361 | 0.017494 |
| 80 |  | $0.528200+12.5541 C-34.3527 \mathrm{C}^{2}$ | 0.9853 | 0.017404 |

[^0]monomer (M), plus the acid groups attributable to the dimer (D). This may be written in equation form as
\[

$$
\begin{equation*}
\text { Total Acid }=M+D \tag{76}
\end{equation*}
$$

\]

It is also known from the reaction stoichiometry, that the total ester groups must be equal to the sum of the dimer ester groups plus the butyl lactate $\left(E_{1}\right)$ ester groups, plus twice the butyllactyllactate ester groups, $\left(E_{2}\right)$, or

$$
\begin{equation*}
\text { Total Ester }=D+E_{1}+2 E_{2} \tag{77}
\end{equation*}
$$

Following the assumed model any reaction of butanol is to form butyl ester. By the model, the only butyl esters formed are butyllactate and butyllactyllactate. Therefore, the decrease in butanol is equal to the sum of the two butyl esters. This may be written as

$$
\begin{equation*}
B_{i}-B=E_{1}+E_{2} \tag{78}
\end{equation*}
$$

where $B_{i}$ is the initial butanol content and $B$ is the final butanol content.

Finally, the butyl lactate content is known by analysis. Change in water content is found by difference, realizing that for every acid group that disappears, one water unit is formed. These balances may be written as

$$
\begin{gather*}
\text { Butyl lactate }=\mathrm{E}_{1}  \tag{79}\\
\mathrm{~W}=\mathrm{W}_{\mathbf{i}}+\text { initial total acid }-\mathrm{P} \tag{80}
\end{gather*}
$$

where $W_{i}$ is initial water content, $W$ is final water content, and $P$ is total acid.

It should be noted that these balances are independent of reaction path and are only based on the formation of the specified reaction products.

These material balances (Eqs. (76), (77), (78), (79), and (80)) were combined and solved for individual component concentrations using the smoothed data equations. These results are presented in Appendix D.

The component concentrations as a function of catalyst concentration were fit by regression to a least squares polynomial of second order. Since the solution of the material balance equations involves the addition and subtraction of the smoothed second order polynomials for the raw data and constants, the resultant component equations should be second order polynomials. That is, since the raw data were expressed as second order polynomials the resultant component concentration must also be perfectly expressed as second order polynomials. The equations for component concentration in moles
per gram versus catalyst concentration are given in Table VIII.

At this point, simplifying assumptions were made about the nature of the reaction scheme. Two possible paths may be followed to determine the reaction kinetics. First, all three suggested reactions may be assumed as occurring to an appreciable extent. That is,

$$
\begin{align*}
& \mathrm{M}+\mathrm{B} \underset{\mathrm{k}_{2}}{\stackrel{\mathrm{k}_{1}}{\rightleftarrows}} \mathrm{E}_{1}+\mathrm{W}  \tag{43}\\
& \mathrm{D}+\mathrm{B} \underset{\mathrm{k}_{4}}{\stackrel{\mathrm{k}_{3}}{\rightleftarrows}} \mathrm{E}_{2}+\mathrm{W}  \tag{44}\\
& \mathrm{E}_{1}+\mathrm{M} \underset{\mathrm{k}_{6}}{\stackrel{\mathrm{k}_{5}}{\rightleftarrows}} \mathrm{E}_{2}+\mathrm{W} \tag{45}
\end{align*}
$$

If the reaction given by equation 45 is significant, the decrease in monomer content should be significantly larger than the increase in butyllactate content. Examination of the component equations in Table VIII reveals that the differences between these relative rates are small and may be assumed statistically insignificant. The assumption that this reaction is negligible is given further merit in light of the kinetics of the reaction of between two monomer groups to yield the dimer. This reaction is extromely slow in the present systen

(Appendix A). The reaction between butyl lactate and monomer is characteristically the same as the dimerization, with the carboxylic acid group of the monomer reacting with the alcoholic group of the ester. If anything, considering the added steric hindrance of the butyl group, this reaction might be expected to be slower than the dimerization. On this basis, as an initial attempt, only the reactions given in equations 43 and 44 were assumed to be important. This assumption was later found to be sound by the excellent correlation of the results obtained, taking only the reactions given by equations 43 and 44 as significant.

The equilibrium constants for the reactions occurring were evaluated at 25 C from five specially prepared samples covering an initial range of alcohol to lactic acid mole-ratio varying from 1.16:1 to 7.25:1; and alcohol to dimer mole-ratio varying from 3.69: 1 to 25.9:1. Uncatalyzed mixtures were used in these evaluations. The equilibrium constant for the esterification of lactic acid was found to be $3.13 \pm .15$. The equilibrium constant for the esterification of lactyllactic acid was found to be $2.75 \pm 0.15$. The equilibrium constants were assumed to be independent of temperature and catalyst concen-
tration, (see page 51-52).

Density correction for conversion of data from unit weight to unit volume was performed using an empirical expression derived by Kaplan (30). The density may be expressed as

$$
\begin{equation*}
y=0.869-0.026 x_{1}-0.010 x_{2}+0.0073 x_{1}^{2} \tag{81}
\end{equation*}
$$

where

$$
\begin{aligned}
\mathrm{y}= & \text { density, grams } / \mathrm{ml} \\
\mathrm{x}_{1}= & \text { coded mole ratio of alcohol to lactic } \\
& \text { acid } \\
\mathrm{x}_{2}= & \text { coded temperature, }{ }^{\mathrm{o}}{ }_{\mathrm{C}}
\end{aligned}
$$

The coding relationsip for $x_{1}$ and $x_{2}$ may be expressed as

$$
\begin{align*}
& x_{1}=-1+(B / M-2.0)  \tag{82}\\
& x_{2}=0.05 T-3.25 \tag{83}
\end{align*}
$$

The component balance equations, equilibrium constants, residence times, density conversion, and reactor design equation were solved to yield the forward observed rate constant as a function of catalyst concentration. These results are presented in Tables $I X$ and $X$, and plotted in Figures 7 and 8. The computer printouts of these results are given in Appendix E.

Figure 8
OBSERVED RATE CONSTANT FOR BUTYLLACTYLLACTATE FORMATION, liter/mole-sec

First order Least Squares polynomials were then fit to these observed rate constants. The intercept of these linear relationships represents the uncatalyzed rate constants, while the slopes of these lines represent the catalyzed rate constants. The catalyzed and uncatalyzed rate constants are presented in Table XI. The computer printouts of the least squares fits are given in Appendix $F$.

Finally, first order least squares polynomials were fit to the catalyzed and uncatalyzed rate constants, using the natural log of the constant versus the reciprocal of the absolute temperature. The slope of this line represents -(E/R), where $E$ is the Arrhenius activation energy. The intercept represents the natural log of the pre-exponential constant, $k_{o}$. The Arrhenius parameters are presented in Table XII. Figure 9 shows the plot of the natural log of the rate constant, $k$ versus the reciprocal of the absolute temperature for the butyllactate and the butyllactyllactate reactions, both catalyzed and uncatalyzed. Computer printouts for the least squares fit of $1 n k$ versus $1 / T$ are given in Appendix $G$. It should be noted in Appendix $G$ that the intercepts, $\ln k_{o}$, should be corrected by adding $\ln \left(10^{-6}\right)$. This factor was not carried

## Verification Runs

To verify the independence of the observed rate constant from the effects of varying alcohol to acid ratio, two additional experimental runs were made subsequent to the experimental series previously discussed. Throughout that series of runs, lactic acid and butanol feed rates to the reactor were maintained constant. Pump head settings were kept at a micrometer reading of 5.0 for both reactant streams. In the two later runs, alcohol to acid feed ratios were varied by maintaining a lactic acid pump setting of 5.0 and varying the butanol setting to 3.0 and 7.0. Except as noted above, the run procedures and analytical techniques discussed in Chapter III were followed.

Both verification runs were made at $80^{\circ} \mathrm{C}$ with no added catalyst. Reactor residence times, reactant feed rates and initial reactant concentrations are given in Table XIII. Also given in Table XIII are the mean values of total acid, total ester, butanol and butyl lactate determined for the reaction products.

The reaction product analyses and initial feed compositions may be combined with the material balances presented previously to yield the individual component concentrations. This was done, and the results are presented in Table XIV.

Finally, the component concentrations, reactor residence time and reaction mass density, (calculated from empirical relationship of Kaplan (30)) may be combined in the reactor design equation to yield the rate constants for the butyl lactate and butyllactyllactate formation. The results of these calculations are given in Table XIV.

Also given in Table XIV are the percentage differences between these values and the values predicted by the Arrhenius parameters previously determined. Agreement between these values is good, thus indicating no relationship between observed rate constant and alcohol to acid mole ratio. For comparison purposes, these values are plotted in Figures 7 and 8.

## CHAPTER IV

## DISCUSSION OF RESULTS

## SUMMARY OF INVESTIGATION

The objective of this investigation was to determine the model for the system of reactions occurring when aqueous solutions of lactic acid are contacted with a primary alcohol. The alcohol selected for use in this study was n-butanol. The choice of butanol was not arbitrary, but was made on the basis of an industrial design proposed by Kaplan (30), for the purification of lactic acid. However, the mechanistic results obtained in this study need not be restricted to butanol alone. The final reaction model should be applicable to any primary alcohol.

Several possible reactions may be postulated as occurring within this system. These include the dimerization of monomeric lactic acid, the reaction of monomeric lactic acid with butanol to form butyllactate, the reaction of dimeric lactic acid with butanol to form butyllactyllactate, and the reaction of monomeric lactic acid with butyllactate to form butyllactyllactate. The sysiem considered as a whole is quite complicated, with parallel and
series reactions occurring simultaneously. The reaction scheme, however, may be simplified considerably on the basis of previous investigations and logical conclusions drawn from an examination of the esterification mechanisms.

The dimerization reaction may be isolated and studied independently. The results of a preliminary investigation performed by Kaplan (30), showed that this reaction proceeds at an extremely slow rate. A thorough investigation of this reaction was performed by this investigator. The experimental data, calculations and results are presented in detail in Appendix A.

Kinetic data for the hydrolysis of the dimer were obtained through the use of an overflow backmix reactor. The raw materials, analytical techniques, experimental equipment configurations and run procedures used were those previously discussed in Chapter II. Experimental data were analyzed in the manner presented in Chapter III.

The resultant functional relationships between the observed rate constants and catalyst concentration within the reaction system were found to be linear. Evaluation of the Arrhenius parameters
indicated that the reaction rate constant could be successfully characterized by the following relationship,

$$
k_{f}=k_{o} e^{-E / R T}+(C) k_{o}^{\prime} e^{-E \prime / R T}
$$

where,

$$
\begin{aligned}
& \mathrm{k}_{\mathrm{f}}=\text { the forward reaction rate constant, } 1 / \mathrm{mole}-\mathrm{sec} \\
& \mathrm{E}=22930 \pm 1617 \mathrm{cal} \\
& \mathrm{E}^{\prime}=12360 \pm 219 \mathrm{cal} \\
& \mathrm{k}_{\mathrm{o}}=(6.307 \pm 1.88) \times 10^{8} 1 / \text { mole-sec } \\
& \mathrm{k}_{\mathrm{o}}^{\prime}=6.821 \pm 0.2531^{2} / \text { mole-sec-mmole catalyst } \\
& \mathrm{C}=\text { catalyst concentration, mmoles/1 }
\end{aligned}
$$

The equilibrium constant for the monomer-dimerwater system was found to be $1.27 \pm 0.07$ at $25^{\circ} \mathrm{C}$, and was assumed to be temperature and catalyst independent. Estimation of the conversion of dimer to monomer in the butanol-lactic acid system showed this reaction to be negligible even in the most severe cases of temperature and catalyst concentration.

The other possible reactions occurring within the system may not be isolated in the manner that the dimerization reaction can. However, conclusions may be drawn about the importance of the reaction between monomeric lactic acid and butyl lactate. It is postulated by the $A_{A C}{ }^{2}$ mechanism
that this reaction is mechanistically similar to the dimerization reaction. The carboxylic acid group of the monomer is reacting with the hydroxyl group of the butyl lactate. The structure of the butyl lactate molecule is similar to the structure of the monomer molecule, but is bulkier due to the added butyl group. This bulkier structure, resulting in increased steric hindrance, might be expected to reduce the rate of this reaction to a rate slower than the dimerization. This analysis allows the conclusion that the monomer-butyl lactate reaction may be neglected within this reaction system. The validity of this conclusion is illustrated by the excellent correlation of data obtained while neglecting this reaction.

Eliminating the above two reaction results in a simplified system. The only reactions occurring are the parallel reactions yielding butyl lactate $\left(E_{1}\right)$ and butyllactyllactate $\left(E_{2}\right)$ from monomer (M) and dimer (D), respectively. That is,

Where $B$ is butanol and $W$ is water.

These reactions are simple acid catalyzed esterifications which may be postulated as occurring
by the standard $A_{A C}{ }^{2}$ mechanism. Once a logical reaction model is available, a methodical approach to the evaluation of the rate constants may begin.

Kinetic data for this system were obtained through the use of an overflow back-mix reactor. The back-mix reactor system allowed the evaluation of a dynamic steady-state sample of reaction product. In total, twenty-four experimental runs were performed, using the butanol-lactic acid system. The resultant data were smoothed using least squares polynomials and correlated by the proposed reaction mode1.

The resultant functional relationships between the observed rate constants and the cuncentration of catalyst within the reaction system were found to be linear. Evaluation of the Arrhenius parameters indicated that the reactions could be successfully characterized by the following relationship

$$
k_{f}=k_{o} e^{-E / R T}+(C) k_{o}^{\prime} e^{-E \cdot / R T}
$$

where, for the reaction of butanol with lactic acid to form butyl lactate,

$$
\begin{aligned}
& \mathrm{k}_{\mathrm{f}}=\text { the forward reaction rate constant, } 1 / \text { mole-sec } \\
& \mathrm{E}=21,220 \mathrm{cal} \pm 715 \mathrm{cal} \\
& \mathrm{E}^{\prime}=10,870 \mathrm{cal} \pm 650 \mathrm{cal}
\end{aligned}
$$

$\mathrm{k}_{\mathrm{o}}=(6.25 \pm 0.97) \times 10^{8} \mathrm{I} / \mathrm{mole}-\mathrm{sec}$
$k_{o}{ }^{\prime}=(8.91 \pm 1.10) 1^{2} /$ mole-sec-mmole catalyst $\mathrm{C}=\mathrm{catalyst}$ concentration, mmoles/l
and for the reaction of butanol with lactyllactic acid to form butyllactyllactate,
$k_{f}=$ the forward reaction rate constant, $1 /$ mole-sec $E=17,580 \mathrm{cal} \pm 300 \mathrm{cal}$
$\mathrm{E}^{\prime}=7,980 \mathrm{cal} \pm 645 \mathrm{cal}$
$k_{o}=(1.303 \pm .08) \times 10^{6} 1 / \mathrm{mole}-\mathrm{sec}$
$k_{o}^{\prime}=(4.54 \pm 0.55) \times 10^{-2} 1^{2} /$ mole-sec-mmole catalyst
The above results were obtained from a series of runs performed at a constant feed molar ratio of alcohol to acid of 2.02:1. To verify these results and to check the independence of observed rate constant with respect to alcohol to acid ratio, two subsequent runs were performed. These runs were made with alcohol to acid molar feed ratios of $1.15: 1$ and 2.72:1, at a temperature of $80^{\circ} \mathrm{C}$ with no added catalyst. The results of these runs are presented in Table XIV. From the Arrhenius parameters presented above, predicted observed rate constants are $45.3 \times 10^{-5} 1 / m o l e-s e c$ for the Eormation of butyllactate, and $17.0 \times 10^{-5} \mathrm{I} / \mathrm{mole}-\mathrm{sec}$ for the formation of butyllactyllactate. Experimental values from the variable alcohol to acid ratio runs were
found to have a maximum error of approximately 11 percent based on the predicted value. The check was quite good. On the basis of these results it may be said that the observed rate constants are functionally independent of the molar feed ratio of butanol to lactic acid.

## DISCUSSION

The reliability of the Arrhenius parameters obtained in this study is a direct function of the accuracy of fit of the least squares polynomials to the raw data. Examination of the standard error of estimate for the least squares polynomials given in Table VII reveals an excellent fit to the data. The maximum error of estimate is of course, most significant in the determination of the butanol and butyl lactate contents of the reactor products. These two quantities control the amounts of butyl lactate and butyllactyllactate obtained by material balance. An analysis of the variability of the Arrhenius parameters with the component material balances may be obtained by examination of the standard error of estimate for these quantities. The deviation of the intercept value of $\ln k_{o}$ for the catalyzed and uncatalyzed reactions in both the butyl lactate and butyllactyllactate formation reactions is equal to plus or minus the 95 percent confidence limit based on the standard error of estimate of $\ln \mathrm{k}$.

The range of activation energy, $E$, may be evaluated about the mean value of the experimental data; that is, at the mean values of the natural log
of the rate constant and the reciprocal temperature. The maximum and minimum values of the slope, $-E / R$, are the lines passing through the mean value and encompassing 95 percent of all experimental data. In the current system, where only three points are available, the lines are drawn passing through the mean value and encompassing the extreme data points. The mean range of the activation energy for all correlations is 6.0 percent.

The confidence area of the correlation can be closely approximated by drawing smooth curves asymptotic to the lines of maximum and minimum slope and through the extremities of the confidence range of the mean value.

An explanation is needed as to the marked difference in Arrhenius parameters for the catalyzed and uncatalyzed mechanisms for both the butyllactate and butyllactyllactate reactions. The $A_{A C}{ }^{2}$ mechanism predicts that both catalyzed and uncatalyzed reactions proceed by the same path. This being the case, one would expect that the irrhenius parameters for catalyzed and uncatalyzed reactions should be approximately the same. The difference most probably arises as a result of the correlation of data in terms of an "uncatalyzed" reaction. As
discussed previously, the application of the analytical expression

$$
\begin{equation*}
\mathrm{k}_{\text {obs }}=\mathrm{k}_{\text {uncat }}+\mathrm{Ck} \text { cat } \tag{42}
\end{equation*}
$$

does not rigorously apply to a system of this type. The "uncatalyzed" reaction, per se, cannot occur. The results obtained in this work are reasonable in light of the fact that at a catalyst concentration of zero added catalyst, some hydrogen ions are present in the reaction system due to dissociation of carboxylic acid groups of the lactic acid and dimer lactic acid.

## COMPARISON OF RESULTS WITH OTHER INVESTIGATIONS

Prior investigations into the kinetics of the esterification of lactic acid with a primary alcohol have been discussed in an earlier section of this report. The empirical correlations of Troupe (56,57, 58), for the esterifications of lactic acid with methanol and ethanol may not realistically be compared to the investigation performed in this work. The results of Troupe's work were derived without theoretical considerations, using alcohols different from the one used here. One result of Troupe's investigation should be mentioned. That is, that the rate constants arrived at by that investigator were different for $44 \%$ (with low dimer content) and $88 \%$ (with high dimer content) lactic acid. These results were obtained assuming no dimer esterification with the alcohol.

The investigation by Kaplan (30) into the kinetics of the esterification of lactic acid with n-butanol was subject to limitations. Initially, that work involved the study of a "synthetic" lactic acid solution. Dimer concentrations were reduced to $4.5-9 \%$, where $35-40 \%$ dimer would be expected at equilibrium. In addition, Kaplan, as did the investigations of Troupe, neglected the dimer
alcohol reaction. The experimental design used by Kaplan was intended to reduce the importance of the dimer-butanol reaction by operating at low dimer contents. However, it is felt by this investigator that in light of the results of this investigation, that a dimer concentration of up to $9 \%$ was not low enough to be negligible. The analysis of the kinetic data taken by Kaplan was therefore confounded by the significant occurrence of both the monomer and dimer esterification reactions. The kinetic parameters resulting from this data are therefore incorrect.

It would be of interest at this point to apply the reaction scheme and kinetic parameters determined by this investigator to the kinetic data found by Kaplan. In his dissertation, Kaplan presents a typical set of experimental data for a sample batch esterification run. The data presented includes initial batch composition data (in terms of weights of reactants added and reactant concentrations) and titration data equivalent to the total acid and total ester per unit mass of sample. Calculated values of lactic acid and butyl lactate concentration are also given. Initial reactor conditions and the various experimental values as a
function of time are presented in Table XV.

The reactor design equation used by Kaplan for correlation of his data is the batch reactor equation solved for a second order reversible reaction. The design equation may be expressed as,

$$
t=\frac{V K_{e q}}{k_{f}} \frac{1}{\sqrt{-q}} \ln \frac{\left(2 c X_{a}+b-\sqrt{-q}\right)(b+\sqrt{-q})}{\left(2 c X_{a}+b+\sqrt{-q}\right)(b-\sqrt{-q})}
$$

where,
$q=4 a c-b^{2}$
$a=K_{e q} N_{\text {No }} N_{B o}-N_{R o} N_{\text {So }}$
$b=-K_{e q} N_{B o}-K_{e q} N_{A O}-N_{R o}-N_{S o}$
$c=K_{e q}-1$
where the terms are defined as
$\mathrm{t}=\mathrm{time}$ elapsed
$k_{f}=$ forward reaction rate constant
$K_{e q}=$ equilibrium constant
$\mathrm{N}_{\mathrm{Ao}}, \mathrm{N}_{\mathrm{Bo}}, \mathrm{N}_{\text {Roo }}, \mathrm{N}_{\mathrm{So}}=$ moles of reactants A and B , and products $R$ and $S$ initially present per unit mass of charge.
$X_{A}=$ moles of $A$ converted to product per unit mass of charge
$V=$ volume of reacting system per unit mass of charge

* Based on initial charge

Equation (84) may be rearranged to the more easily workable form,

$$
\begin{equation*}
x_{A}=\frac{\left(b^{2}+q\right)\left(1-e^{k}\right)}{2 c\left(b e^{k}-\sqrt{-q} e^{k}-b-\sqrt{-q}\right)} \tag{85}
\end{equation*}
$$

where

$$
\begin{equation*}
K=\frac{t k_{f} \sqrt{-q}}{V k_{e q}} \tag{86}
\end{equation*}
$$

Equations (85) and (86) may be combined with the initial component concentrations as given by Kaplan and the rate constants and equilibrium constants determined by this investigator, to determine the conversion as a function of time of the initial monomeric and dimeric lactic acids. The computer program for the solution of equation (85) and (86) as well as the predicted butyl lactate and butyllactyllactate values obtained are given in Appendix H. Material balances may then be applied to calculate the monomer content and total acid and ester values as a function of time. A tabulation of these results for comparison to Kaplan's are presented in Table XV.

Initially it must be pointed out that certain assumptions have been made in the calculation of the predicted values. This calculation is based on the weights of reactants charged to the reactor and the
component concentrations given for these reactants. The individual component concentrations given in Table XV are those based on the initial charge. However, there is a discrepancy between these values and the values presented by Kaplan as data. For example, based on the initial charge, the total acid plus ester groups in the batch is 4.533 moles $/ \mathrm{kg}$. The only reactions occurring in the system are esterifications, such that each acid group reacting results in the formation of one ester group. The total acid plus ester content should be constant. From Kaplan's data, the acid plus ester total is equal to 4.308 moles/kg. In addition, based on initial charge, monomer content is 4.285 moles $/ \mathrm{kg}$. Since the reaction of monomer results only in the formation of butyl lactate, the total of monomer plus butyl lactate should equal a constant. It is a constant for Kaplan's data, but the constant is equal to 3.904 moles/kg.

Two possible conclusions may be drawn from the above discrepancies. Either the weights of the initial charge are in error or the analysis of the product samples are in error. These possibilities shall be discussed qualitatively as to their effects on the comparative predicted and experimental
values.

For the first case, an error in inital charge weights, the indication from the data is that the initial charge would have contained less lactic acid. If this were the case, the conversion to butyl lactate would be lower due to the lower initial concentration of the monomer. This would tend to bring the predicted values more in line with the experimental values of Kaplan.

The second possibility is that the experimental. data is in error, resulting from an error in analytical technique. It was found by this investigator that a truly reproducible determination of ester content by saponification, required the samples to be heated for a minimum of two hours in a hot water bath at $90^{\circ} \mathrm{C}$. Three hours of heating were taken as standard in this investigation. The technique used by Kaplan involved heating at $90^{\circ} \mathrm{C}$ for only 15 minutes. That procedure was initially tried by this investigator and it was found that fairly reproducible results could be obtained so long as the saponification time was maintained constant. However, the results were not reproducible as a function of time until at least two hours of saponification timewere allowed. On this basis, it may be
surmised that the saponification results reported by Kaplan may not be a true measure of the total ester content of the sample.

The effect of this error would be two-fold. First the analysis of the feed lactic acid used by Kaplan should be higher in dimer content and lower in monomer content. This would tend to give lower butyl lactate concentrations than would be predicted. This is consistent with the observations in Table XV.

Secondly, the experimental total ester determination should be higher. This would again tend to bring the predicted values closer in line with what might be expected experimentally.

In summary, it may be said that discrepancies were found in the experimental data reported by Kaplan. Any explanation of these discrepancies that may be offered serves to indicate, at least qualitatively, an agreement between the data of Kaplan and the results of the correlations of the current investigation. In light of this, it may be said that the experimental data found by Kaplan are consistent with the results found by this investigator.

## CHAPTER V

## CONCLUS IONS

1. The significant reactions occurring when an aqueous lactic acid solution and a primary alcohol are contacted are the esterification of monomeric lactic acid and the esterification of the dimeric lactic acid with the alcohol. The reactions may be represented as
monomer + alcohol $=$ ester of monomer + water
dimer + alcohol $=$ ester of dimer + water
In the system investigated, the alcohol was nbutanol with the esters formed being butyl esters.
2. The kinetic parameters for the butyl lactate formation reaction

$$
\mathrm{CH}_{3} \mathrm{CHOHCOOH}+\mathrm{C}_{4} \mathrm{H}_{9} \mathrm{OH} \rightleftarrows \mathrm{CH}_{3} \mathrm{CHOHCOOC}_{4} \mathrm{H}_{9}+\mathrm{H}_{2} \mathrm{O}
$$

can be represented as

$$
k_{f}=k_{o} e^{-E / R T}+C k_{o}^{\prime} e^{-E^{\prime} / R T}
$$

where

$$
\begin{aligned}
& \mathrm{k}_{\mathrm{f}}=\text { the forward rate constant, } 1 / \mathrm{mole}-\mathrm{sec} \\
& \mathrm{E}=21,220 \mathrm{cal} \pm 715 \mathrm{cal} \\
& \mathrm{E}^{\prime}=10,870 \mathrm{cal} \pm 650 \mathrm{cal} \\
& \mathrm{k}_{\mathrm{o}}=(6.258 \pm 0.97) \times 10^{8} \quad 1 / \mathrm{mole-sec}
\end{aligned}
$$

$\mathrm{k}_{\mathrm{o}}{ }^{\prime}=(8.91 \pm 1.10) 1^{2} /$ mole-sec-mmole cat
$\mathrm{C}=$ catalyst concentration, mmoles/1
3. The equilibrium constant for the reaction resulting in the formation of butyllactate was $3.13 \pm 0.16$, evaluated at 25 C .
4. The kinetic parameters for the butyllactyllactate formation reaction
$\mathrm{CH}_{3} \mathrm{CHOHCOOCH}\left(\mathrm{CH}_{3}\right) \mathrm{COOH}+\mathrm{C}_{4} \mathrm{H}_{9} \mathrm{OH} \rightleftarrows$

$$
\mathrm{CH}_{3} \mathrm{CHOHCOOCH}\left(\mathrm{CH}_{3}\right) \mathrm{COOC}_{4} \mathrm{H}_{9}+\mathrm{H}_{2} \mathrm{O}
$$

can be represented by the above relationsip, where
$\mathrm{k}_{\mathrm{f}}=$ the forward rate constant, $1 / \mathrm{mole}-\mathrm{sec}$
$\mathrm{E}=17,580 \mathrm{cal} \pm 300 \mathrm{cal}$
$E^{\prime}=7,980 \mathrm{cal} \pm 645 \mathrm{cal}$
$\mathrm{k}_{\mathrm{o}}=(1.303 \pm .08) \times 10^{6} 1 /$ mole-sec
$\mathrm{k}_{\mathrm{o}}^{\prime}=(4.54 \pm 0.55) \times 10^{-2} 1^{2} /$ mole-sec-mmoles cat
$\mathrm{C}=$ catalyst concentration, mmoles/1
5. The equilibrium constant for the esterificaLion of lactyllactic acid was $2.75 \pm 0.15$, evaluated at 25 C .
6. The kinetic parameters for the hydrolysis of dimetric lactic acid,
$\mathrm{CH}_{3} \mathrm{CHOHCOOCH}\left(\mathrm{CH}_{3}\right) \mathrm{COOH}+\mathrm{H}_{2} \mathrm{O} \rightleftarrows 2 \mathrm{CH}_{3} \mathrm{CHCHCOOH}$
may be represented as

$$
k_{f}=k_{o} e^{-E / R T}+C k_{o} e^{-E / R T}
$$

where

$$
\begin{aligned}
& \mathrm{k}_{\mathrm{f}}=\text { the forward rate constant, } 1 / \text { mole-sec } \\
& \mathrm{E}=22,930 \pm 1617 \mathrm{cal} \\
& \mathrm{E}^{\prime}=12,360 \pm 219 \mathrm{cal} \\
& \mathrm{k}_{\mathrm{O}}=(6.307 \pm 1.88) \times 10^{8} 1 / \mathrm{mole}-\mathrm{sec} \\
& \mathrm{k}_{\mathrm{O}}^{\prime}=6.821 \pm 0.2531^{2} / \mathrm{mole}-\mathrm{sec}-\mathrm{mmole} \mathrm{cat} \\
& \mathrm{C}=\text { catalyst concentration, mmoles/1 }
\end{aligned}
$$

7. The equilibrium constant for the hydrolysis of lactyllactic acid was $1.27 \pm 0.07$ evaluated at 25 C with no added catalyst.

## CHAPTER VI

## RECOMMENDATIONS

1. The kinetic parameters of the esterification reactions may be used to design a pilot scale system, for the continuous production of lactic acid.
2. The kinetic parameters of the esterification reactions may be used in an economic balance of an industrial design for the purification of lactic acid.
3. An investigation should be performed into the ionization of lactic acid in butanol-waterlactic acid systems to determine the ionization constant as a function of composition and temperature. Once this is done, the hydrogen ion concentration in an "uncatalyzed" reaction system may be calculated and the true single value of the "catalyzed" rate constant may be determined.

## APPENDIX A

## MONOMER-DIMER REACTION

The hydrolysis of an aqueous 80 percent lactic acid solution with water was studied at three temperature levels and varying catalyst levels to evaluate the kinetic parameters of the reaction:
$\mathrm{CH}_{3} \mathrm{CHOHCOOCH}\left(\mathrm{CH}_{3}\right) \mathrm{COOH}+\mathrm{H}_{2} \mathrm{O} \longleftrightarrow 2 \mathrm{CH}_{3} \mathrm{CHOHCOOH}$
A preliminary investigation by Kaplan (30)had indicated that the self esterification of lactic acid was extremely slow and the effects of this reaction, relative to the esterification of lactic acid with $n$-butanol, were negligible. The scope of current investigation was to verify Kaplan's observations and to fully determine the kinetic parameters of the monomer-dimer reaction.

The raw materials, analytical techniques, experimental equipment configurations, and run procedures discussed in Ghapter II were used throughout this series of runs. Experimental data were analyzed in the manner presented in Chapter III. A step by step procedure for data analysis is presented below.

## Experimental Results

The hydrolysis of lactyllactic acid was in-
vestigated at temperature levels of $59^{\circ} \mathrm{C}, 67^{\circ} \mathrm{C}$, and $77^{\circ} \mathrm{C}$ and at catalyst concentrations ranging from zero to approximately 35 moles/liter. Reaction was performed in an overflow backmix reactor with volumetric input rates maintained constant. Reactor residence times varied slightly with the reaction temperature and the composition of the product stream. Experimental residence times were 1454 sec at $59^{\circ} \mathrm{C}, 1396 \mathrm{sec}$ at $67^{\circ} \mathrm{C}$, and 1340 sec at $77^{\circ} \mathrm{C}$.

The mean total acid data for the run series are tabulated in Table A-1. This raw experimental data were fit with least squares polynomials to smooth experimental fluctuations. Summary computer printouts for all experiments, showing the actual data, predicted data and the percent difference between the two are given in Tables A-2, A-3 and A-4. The resultant polynomials are presented in Table A-5.

## Material Balances

Consistent with the reaction model given above, and with the knowledge of initial feed compositions, material balances may be written to determine the amounts of the various components within the reaction mass.

It is known from the reaction stoichiometry that the total acid (corrected for catalyst content), must be equal to the acid groups attributable to the monomer (M), plus the acid groups attributable to the dimer (D). It is also known from the reaction stoichiometry that each dimer molecule reacting results in two monomer molecules with a net increase of one acid group. Therefore, it may be said that

$$
\begin{aligned}
& \text { increase in monomer/gram }=(2) \text { (increase in acid/gram) } \\
& \text { decrease in dimer/gram }=\text { increase in acid/gram } \\
& \text { decrease in water/gram }=\text { increase in acid/gram }
\end{aligned}
$$

thus, the following material balances may be written:

$$
\begin{aligned}
& \text { final monomer }=\text { initial monomer }+(2)(\Delta a c i d / g r a m) \\
& \text { final dimer }=\text { initial dimer- } \Delta a c i d / g r a m \\
& \text { final water }=\text { initial water- } \Delta a c i d / g r a m
\end{aligned}
$$

where
$\Delta a c i d=(f i n a l$ total acid/gram)-(initail total acid/gram)
The equilibrium constant for the monomer-dimerwater system was found to be $1.27 \pm .07$ at $25^{\circ} \mathrm{C}$. This constant was evaluated from multiple analyses of the feed lactic acid. The equilibrium constant was assumed to be independent of temperature and catalyst concentration.

Initial flow conditions and feed concentrations, which were maintained constant throughout the series of runs, are tabulated in Table A-6. This information, combined with the material balances given above and the smoothed raw data, yields the component concentrations as a function of catalyst concentration. The component concentrations may be combined with the reactor design equation to calculate the forward reaction rate constant as a function of catalyst concentration. These results were calculated at one time with the aid of the computer. A typical computer program for this calculation is given in Table $A-7$. The computer printouts of the results are given in Tables $\mathrm{A}-8$ and $\mathrm{A}-9$ and $\mathrm{A}-10$. A plot of calculated observed rate constant versus catalyst concentration is shown in Figure 10.

The observed rate constants versus catalyst concentration data were fit with a first order least squares polynomials. These results are tabulated in Table A-11, where the intercepts are equal to the uncatalyzed rate constants and the slopes are equal to the catalyzed rate constants.

Finally, first order least squares polynomials were fit to the uncatalyzed and catalyzed rate con-
stants, using the natural log of the constant versus the reciprocal of the absolute temperature. The slope of this line represents -(E/R), where E is the Arrhenius activation energy. The intercept represents the natural log of the pre-exponential constant, $k_{o}$. The Arrhenius parameters are presented in Table A-12. Figure 11 is a plot of the natural $\log$ of the rate constant, $k$ versus the reciprocal of the absolute temperature. Computer printouts for the least squares fit of $1 n k$ versus $1 / T$ are given in Tables $A-13$ and $A-14$.

## Discussion

Kinetic data for this system were obtained through the use of an overflow back-mix reactor. In total, seventeen experimental runs were performed, using the lactic acid-water system. The resultant data were smoothed using least squares polynomials and correlated by the proposed reaction mode1.

The resultant functional relationships between the observed rate constants and the catalyst concentration within the reaction system were found to be linear. Evaluation of the Arrhenius parameters indicated that the reaction rate constant could be successfully characterized by the following relationship

$$
k_{f}=k_{o} e^{-E / R T}+(C) k_{o}^{\prime} e^{-E \cdot / R T}
$$

where,

$$
\begin{aligned}
& \mathrm{k}_{f}=\text { the forward reaction rate constant, } 1 / \mathrm{mole}-\mathrm{sec} \\
& \mathrm{E}=22,930 \pm 1617 \mathrm{cal} \\
& \mathrm{E}^{\prime}=12,360 \pm 219 \mathrm{cal} \\
& \mathrm{k}_{\mathrm{O}}=(6.307 \pm 1.88) \times 10^{8} 1 / \text { mole-sec } \\
& k_{o}^{\prime}=6.821 \pm 0.2531^{2} / \text { mole-sec-mmole cat. } \\
& C=\text { catalyst concentration, moles/l }
\end{aligned}
$$

The equilibrium constant for the mononer-dimerwater system was found to be $1.27 \pm 0.07$ at $25^{\circ} \mathrm{C}$, and was assumed to be temperature and catalyst independent.

No complete comparison may be drawn between this work and the previous preliminary investigation of Kaplan (30). Kaplan performed runs at varying catalyst concentrations at one temperature only and was therefore unable to evaluate the Arrhenius parameters of the system. A cursory comparison may be drawn from the observed rate constants evaluated by Kaplan. The functional relationship between observed rate constant and catalyst concentration found by Kaplan at 80.4 C may be expressed as,

$$
\mathrm{k}_{\mathrm{o}}=1.93 \times 10^{-6}+\left(1.82 \times 10^{-6}\right) \mathrm{C}
$$

The like expression, evaluated by this investigator at $77{ }^{\circ} \mathrm{C}$, was found to be,

$$
\mathrm{k}_{\mathrm{o}}=2.85 \times 10^{-6}+0.129 \times 10^{-6} \mathrm{C}
$$

The agreement, in terms of uncatalyzed rate constant is fairly good. Agreement in terms of catalyzed rate constant is poor, being different by an order of magnitude. The effect of catalyst found by this investigator is much less pronounced than the effect found by Kaplan. No explanation is
offered for this discrepancy.

The importance of the monomer-dimer reaction during the butanol-1actic acid esterification may be measured by calculating the amount of dimer that would react in the alcohol acid system. The dimer hydrolysis would be most rapid at the highest temperature and higher catalyst concentrations used during the alcohol-acid runs. This occurred during the alcohol run series at 80 C with a catalyst concentration of approximately 50 moles/1. Reactor residence time was 1244 sec . Based on the Arrhenius parameters given in Table A-12 and a catalyst concentration of 50 mmoles/l, the observed rate constant is approximately $9.3 \times 10^{-6} 1 /$ mole-sec.

The initial component concentrations in the alcohol system based on feed rates are,

$$
\begin{aligned}
& \text { Initial Dimer } \quad 1.226 \text { moles } / \mathrm{g} \\
& \text { Initial Monomer } \\
& \text { Initial Water } \\
& 2.91 \text { mmoles } / \mathrm{g} \\
& 5.83 \text { mmoles } / \mathrm{g}
\end{aligned}
$$

Density of the reaction mass is $0.893 \mathrm{~g} / \mathrm{ml}$. Using this data and the reactor design equation, the concentration of dimer (assuming the case of no other competing reactions) may be calculated. This has been done and the exit dimer concentration was found
to be 1.219 mmoles/g. Dimer disappearance by the monomer-dimer reaction was 0.007 moles/g, or 0.57 percent of the feed dimer. On the basis of these calculations it is assumed that the monomerdimer reaction is negligible in the lactic acidbutanol reaction system.

## APPENDIX B

## EXPERIMENTAL DATA

Throughout the course of this investigation, except where noted to the contrary, component feed rates to the reactor were maintained constant. Variation in pumping rates was found to be less than 1.0 percent as determined by periodic checks of component pumping rates. The volumetric feed rates and initial component concentrations, based on these feed rates are given below:

$$
\begin{aligned}
& \text { volumetric feed rate of lactic acid-14.188 } \mathrm{ml} / \mathrm{min} \\
& \text { volumetric feed rate of butanol - } 15.606 \mathrm{ml} / \mathrm{min} \\
& \text { initial lactic acid- } 0.2617 \mathrm{~g} / \mathrm{g}-\text { feed } \\
& \text { initial dimer }-0.1988 \mathrm{~g} / \mathrm{g}-\text { feed } \\
& \text { initial butanol }-0.4344 \mathrm{~g} / \mathrm{g}-\mathrm{feed} \\
& \text { initial water }-0.1050 \mathrm{~g} / \mathrm{g}-\mathrm{feed}
\end{aligned}
$$

The initial component concentrations in terms of moles may be obtained by multiplication by the proper molecular weights.

The remainder of this Appendix lists the experimental data obtained in this investigation given in terms of total acid, corrected for catalyst, total ester, butanol and butyllactate, all in mmoles/gram as a function of catalyst concentration.
