# ABSTRACT <br> THERMOCHEMISTRY AND KINETICS IN PYROLYSIS AND OXIDATION REACTIONS OF OXYGENATED CHLOROCARBONS, NEOPENTANE AND ORTHO-XYLENE 

by<br>Hongyan Sun

Thermochemical properties of chlorinated alcohols, chlorinated hydroperoxides and corresponding alkoxy, hydroxy alkyl radicals, peroxy and hydroperoxy alkyl radicals are determined by $a b$ initio and density functional calculations for modeling and optimization of complex chemical processes for combustion or incineration of chlorinated hydrocarbons. The entropy and heat capacities from vibrational, translational, and external rotational contributions are calculated by statistical mechanics, and the hindered rotational contributions to $S^{0}{ }_{298}$ and $C_{p}(T)$ 's are calculated by using direct integration over energy levels of the internal rotational potentials. The values of $\Delta H_{\mathrm{f}}^{\mathrm{o}} 298$ are determined using isodesmic reactions with group balance. Groups for use in Benson type additivity estimations are determined for the carbon bonded to oxygen and chlorine(s). Hydrogen bond increment groups for the chloroalkoxy, hydroxy chloroalkyl radicals and interaction terms for peroxy group with chlorine(s) are developed for group additivity approach.

The reactions of alkyl radical with oxygen are important rate controlling processes in the low and intermediate temperature chemistry of hydrocarbon oxidation, especially the chemistry which occurs prior to ignition in internal combustion engines and in cool flames. Thermochemical properties for reactants, intermediates, products and transition states in neopentyl radical $+\mathrm{O}_{2}$ reaction system are analyzed with ab initio and density functional calculations to evaluate reaction paths and oxidation kinetics. Rate
constants to products and stabilized adducts of the chemically activated neopentyl-peroxy are calculated as function of pressure and temperature using Quantum Rice-RamspergerKassel analysis for $k(E)$ and a master equation analysis for pressure fall-off. An elementary reaction mechanism is constructed to model experimental OH and $\mathrm{HO}_{2}$ formation profiles.

Aromatic compounds are an important component of higher-octane automotive fuels and consequently they are present in emissions from incomplete combustion and other evaporation from solvents and fuels handling and storage. Oxidation reactions of ortho-xylene are studied to identify the important reaction channels of this class of highoctane aromatics. Elementary reactions, energy well depths, and absolute rate constants of benzylic radical derived from ortho-xylene, 2-methylbenzyl radical with $\mathrm{O}_{2}$, are determined with computational chemistry at density functional levels.

THERMOCHEMISTRY AND KINETICS IN PYROLYSIS AND OXIDATION REACTIONS OF OXYGENATED CHLOROCARBONS, NEOPENTANE AND ORTHO-XYLENE

To

Dr. Joseph W. Bozzelli

who introduced me to the field of thermochemical kinetics during my graduate study at New Jersey Institute of Technology

## ACKNOWLEDGEMENT

The research in this thesis would have taken far longer to complete without the encouragement and help from many others. It is a delight to acknowledge those who have supported me over the last three years.

I wish to express my exceptional appreciation to my dissertation advisor, Dr. Joseph W. Bozzelli, for his professional guidance, thoughtful insight, encouragement, patience, and kindness. I am deeply indebted to him for the opportunities that he made available to me.

I would like to thank to my dissertation committee members, Dr. Lev N. Krasnoperov, Dr. Tamara M. Gund, Dr. Sanjay V. Malhotra, and Dr. Edward R. Ritter for their critical corrections and comments.

This research was supported by the USEPA Northeast Regional Research Center and the USEPA Airborne Organics Research Center. This work would not have been possible without these supports.

The days would have passed far more slowly without the support of my colleagues at NJIT, especially, Dr. Chiung-Chu Chen, who provided such a rich source of friendship, assistance, and conversation, and made my time at NJIT much more enjoyable and productive.

Finally, I wish to thank for my parents, my husband, and my son for their love, patience, and strong support throughout my academic studies.

## CHAPTER 1

## THERMOCHEMICAL KINETICS

### 1.1 Introduction

Detail kinetic models using reaction mechanisms comprised of many elementary chemical reaction steps, based upon fundamental thermochemical and kinetic principles, are presently used and being developed by researchers attempting to optimize or more fully understand a number of chemical complex systems. These systems include combustion, flame inhibition, ignition, atmospheric smog formation, stratospheric ozone depletion, municipal and hazardous wastes incineration, chemical vapor deposition, semiconductor etching, rocket propulsion and other related fields.

One important requirement for modeling and simulation of these systems is accurate thermochemical property data such as enthalpies of formation $\left(\Delta H_{\mathrm{f}}{ }_{2}{ }^{0}\right.$, ), entropy $\left(S_{298}^{0}\right)$, and heat capacities as functions of temperature $\left(C_{p}(T)\right.$ 's) for reactants, intermediates, final products, and reaction transition states. These data allow determination of equilibrium, and reverse rate constants from the forward rate constant and the equilibrium constant. $A b$ initio and density functional calculations provide an opportunity to accurately calculate these thermochemical properties data which are often difficult or impossible to obtain through experiment.

### 1.2 Computational Chemistry

$A b$ initio molecular orbital theory is concerned with predicting the properties of atomic and molecular systems. It is based upon the fundamental laws of quantum mechanics and a variety of mathematical transformation and approximation techniques to solve the fundamental equations, i.e. Schrödinger equation,

$$
\hat{\mathrm{H}} \Psi=\mathrm{E} \Psi
$$

Here $\hat{\mathrm{H}}$ is the Hamiltonian, a differential operator representing the total energy. E is the numerical value of the energy of the state, i.e., the energy relative to a state in which the constituent particles (nuclei and electrons) are infinitely separated and at rest. $\Psi$ is a many-electron wavefunction, and it depends on the Cartesian coordinates of all particles and also on the spin coordinates. The square of the wavefunction, $\Psi^{2}$, is the probability distribution of the particles within the molecule.

The many-electron Schrödinger equation cannot be solved exactly, and approximations need to be introduced to provide practical methods. The approximation of separating electronic and nuclear motions is Born-Oppenheimer approximation that is basic to quantum chemistry. The Hartree-Fock (HF) approximation treats electron interactions between individual electrons by interactions between a particular electron and the average field created by all the other electrons. The HF model does not include a full treatment of the effects of instantaneous electron correction, i.e. it does not include the energy contributions arising from electrons interacting with one another. This leads to overestimation of the electron-electron repulsion energy and to too high a total energy. ${ }^{1}$ Electron correction accounts for coupling or correction of electron motions, and leads to a lessening of the electron-repulsion energy and also leads to a lowering of the total energy.

The correction energy is defined as the difference between the Hartree-Fock energy and the experimental energy. A variety of theoretical methods, such as density functional, configuration interaction, and Møller-Plesset perturbation have been developed which include some effects of electron correction. Density functional models introduce an "approximate" correction term in an explicit manner, and they reduce computational cost than Hartree-Fork models. Configuration interaction models and Møller-Plesset models extend the flexibility of Hartree-Fock models by mixing ground-state and excited-state wavefunctions. They are significantly more costly than Hartree-Fock models. Traditionally, such methods are referred as post-SCF methods because they add this electron correlation correction to the basic Hartree-Fock model.

The density functional theory (DFT) is based on the fact that the sum of the exchange and correlation energies of a uniform electron gas can be calculated exactly knowing only its electron density. These DFT functionals partition the ground state electronic energy into several components: the kinetic energy, the electron-nuclear interaction, the Coulomb repulsion, and an exchange-correlation term, which accounts for the remainder of the electron-electron interactions. ${ }^{2}$ A variety of functionals have been defined, generally distinguished by the way that they treat exchange and correlation components: (1) Local exchange and correlation functions based on the local spin density approximation. (2) Gradient-corrected functionals based on the generalized gradient approximation or Hartree-Fock exchange functional. ${ }^{3}$

Any exchange functional can be combined with any correlation functional. A commonly used gradient-corrected exchange functional is proposed by Becke, ${ }^{4}$ and gradient-corrected correlation functional is the Lee, Yang and Parr (LYP) correlation
functional. The combination of the two functionals forms the B-LYP method. The notation B3LYP denotes a DFT calculation with the Becke functional and the Lee-YangParr correlation functional.

Configuration Interaction (CI) models calculate the correlation energy by mixing the ground-state (Hartree-Fock) wavefunction with "excited-state" wavefunctions. The configuration functions in a CI calculation are classified as singly excited, doubly excited, triply excited, $\ldots$, according to whether $1,2,3, \ldots$ electron are excited from occupied to unoccupied orbitals. It is reported that the first-order correction to the unperturbed (Hartree-Fock) wavefunction of a closed-shell state contains only double excited configuration functions, and the second-order correction to the Hartree-Fock function includes single, double, triple, and quadruple excitations. ${ }^{1}$ The singly excited configuration functions are less important than double excitations in affecting the wave function, but single excitations have a significant effect on one-electron properties. Therefore single excitations are usually included in a CI calculation, and the most common type is CISD calculation which includes the singly and doubly excited configuration functions. ${ }^{5}$ The $\mathrm{CISD}(\mathrm{T})$ method also includes the triple excited functions.

Another correction energy scheme is the second-order Møller-Plesset (MP2) model proposed by Møller-Plesset in 1934. The MP2 is a perturbation treatment of atoms and molecules in which the unperturbed wave function is the Hartree-Fock function. The perturbation is the difference between the true interelectronic repulsions and the HartreeFock interelectronic potential, and the molecular energy is taken as Hartree-Fock energy plus MP2 energy correction. The MP2 calculation are much fast than the CI calculations, but for species involving open-shell ground states, unrestricted SCF wave functions are
not eigenfunction of the total spin operator $\hat{S}^{2}$, and this "spin contamination" can sometimes produce serious errors in UMP-calculated quantities.

Currently available functionals in DFT can not compute a thermodynamic energy such as heat of atomization and the enthalpy of formation with accuracy of $1 \mathrm{kcal} / \mathrm{mol}$. High level configuration interaction methods with large basis sets can do this but too costly to be feasible except for small molecules. The composite CBS method ${ }^{6}$ is reported to achieve $1 \mathrm{kcal} / \mathrm{mol}$ accuracy with a computational time that allows calculation on molecules containing several nonhydrogen atoms. ${ }^{7}$ The CBS methods use special procedures designed to extrapolate calculated energies to the complete-basis-set limit. The CBS methods include several corrected calculations done at a geometry optimized at a lower level of theory. The highest-level calculation used is the $\operatorname{QCISD}(\mathrm{T}) / 6-31+\mathrm{G}(\mathrm{d}, \mathrm{p})$ in the CBS-Q method.

Model chemistry is characterized by the combination of theoretical procedure and a basis set. A basis set is a mathematical representation of the molecular orbitals within a molecule. The basis set can be interpreted as restricting each electron to a particular region of space. Large basis sets impose fewer constraints on electrons to particular accurately approximate exact molecular orbitals. However, the computation of atomic or molecular properties with large basis sets requires correspondingly more and more computational resources.

Standard basis sets for electronic structure calculation use linear combinations of Gaussian functions to form the orbitals. Basis sets assign a group of basis functions to each atom within a molecule to approximate its orbitals. These basis functions themselves are composed of a linear combination of Gaussian functions. The linear
combined basis functions are refereed to as contracted functions, and the component Gaussian functions are referred to as primitives. A basis function consisting of a single Gaussian function is termed uncontracted. In the nomenclature of $6-31 \mathrm{G}$ basis set, " 6 " stands for using 6-component type d function, "31" stands for using two sets of function in the valence region (one function consisting of 3 primitive Gaussian, one consisting of 1 primitive Gaussian).

The $6-31 \mathrm{G}(\mathrm{d}, \mathrm{p})$ indicates that it is the polarized $6-31 \mathrm{G}$ basis set with one d function added to the heavy atoms and one p function added to hydrogen atoms. The 6$311+\mathrm{G}(3 \mathrm{df}, 2 \mathrm{p})$ is the basis set with diffuse functions added to heavy atoms, as well as three d functions and one f function added to heavy atoms, and 2 p functions added to the hydrogen atoms. If $6-311++G(3 d f, 2 p)$, then it also adds diffuse functions to hydrogen atoms. ${ }^{2}$

### 1.3 Kinetics

Several important aspects are needed in order to understand the kinetics of unimolecular reactions. These include: (1) the formation of an energized molecule with energy $E$, (2) the intramolecular vibrational / rotational motion of high energized molecules; (3) unimolecular rate constants for dissociation of the energized molecules as a function of their energy $k(E)$; (4) intramolecular energy transfer to and from highly energized molecules; and (5) energy partitioning between unimolecular dissociation fragments.

There are a number of different theories to present these topics such as Lindemann-Hinshelwood theory, Slater theory, RRK theory, RRKM theory, and Quantum RRK theory. This section will focus on unimolecular reactions, and also discuss chemical activation reactions, which is of great importance to unimolecular reactions.

### 1.3.1 Lindemann-Hinshelwood Mechanism for Unimolecular Reactions

In 1922, Lindemann ${ }^{8}$ proposed a general theory for the thermal unimolecular reaction, which forms the basis for the current theory of thermal unimolecular rates. He proposed that a certain fraction of molecules become energized by bimolecular collisions, i.e. gain energy in excess of a critical quantity $\mathrm{E}_{0}$; the rate of the energy transfer depends upon the rate of bimolecular collisions, and the energized molecules are also de-energized by collision; there is a time lag between the moment of collision energy transfer and the time the molecule decomposes, and an energized molecule can undergo deactivating collisions before decomposition occurs in this time period; this unimolecular dissociation occurs with a rate constant independent of the energy content of the energized molecules, i.e., all molecules with energy above threshold $E_{0}$ dissociate with the same energy. The mechanism in Lindemann theory is written as:

$$
\begin{aligned}
& \mathrm{A}+\mathrm{M} \xrightarrow{k 1} \mathrm{~A}^{*}+\mathrm{M} \\
& \mathrm{~A}^{*}+\mathrm{M} \xrightarrow{k-1} \mathrm{~A}+\mathrm{M} \\
& \mathrm{~A}^{*} \xrightarrow{k 2} \text { Products }
\end{aligned}
$$

The asterisk represents that a molecule A contains sufficient energy to react with collider M . It is assumed that each $\mathrm{A}^{*}+\mathrm{M}$ collision is "strong" and thus leads to deenergizing of A ; this is known as "strong collision assumption" for de-energizing collisions. Therefore, this de-energized rate is taken to be energy-independent and is equated with the collision number $Z_{1}$ by assuming that every collision of $A^{*}$ leads to a deenergized state.

The overall concept can be expressed by the equations below, where M can represent a generic bath gas molecule ("inert" gas molecule); it may also represent a
second molecule of reactant or product. In the simple Lindemann theory $k_{1}$, along with $k_{-1}$ and $k_{2}$ are taken to be energy-independent and are calculated from the simple collision theory equation.

Application of the steady-state hypothesis to the concentration of $\mathrm{A}^{*}$, allows the unimolecular rate constant and the high- and low-pressure limit rate and rate constants to be determined as follows:

$$
\begin{aligned}
& \text { Rate }=k_{\text {uni }}[\mathrm{A}]=k_{2}\left[\mathrm{~A}^{*}\right]=\frac{k_{1} k_{2}[\mathrm{~A}][\mathrm{M}]}{k_{-1}[\mathrm{M}]+k_{2}} \\
& k_{\mathrm{uni}}=k_{1} k_{2} \frac{k_{1} k_{2}[\mathrm{M}]}{k_{-1}[\mathrm{M}]+k_{2}}
\end{aligned}
$$

High-pressure limit rate, $[\mathrm{M}] \rightarrow \infty, k_{\mathrm{uni}}=k_{\infty}=\frac{k_{1} k_{2}}{k_{-1}}$
Low-pressure limit rate, $[\mathrm{M}] \rightarrow 0, k_{\mathrm{uni}}=k_{0}=k_{1}[\mathrm{M}]$
The unimolecular rate constant is then written as: $k_{\mathrm{uni}}=\frac{k_{\infty}}{1+k_{\infty} / k_{l}[\mathrm{M}]}$

One can expect the Lindemann theory to predict a linear change in the initial rate of a unimolecular reaction with respect to concentration of $M$ at low pressure. The transition from high-pressure rate constant to low pressure is called "fall-off region". The $k_{1}$ in the original Lindemann theory is taken from collision theory:

$$
k_{1}=Z_{1} \exp \left(-\frac{E_{0}}{k_{\mathrm{B}} T}\right)
$$

where $Z_{1}=\left(\frac{\sigma_{\mathrm{d}}{ }^{2} \mathrm{~N}_{\mathrm{A}}}{\mathrm{R}}\right)\left(\frac{8 \pi \mathrm{~N}_{\mathrm{A}} k_{\mathrm{B}}}{\mu}\right)^{1 / 2}\left(\frac{1}{\mathrm{~T}}\right)^{1 / 2}$. The unit for $\mathrm{Z}_{1}$ is in $\operatorname{Torr}^{-1}-\mathrm{s}^{-1}$ (consistent with [M] in Torr and $k_{2}$ in $\mathrm{s}^{-1}$ ). $\sigma_{\mathrm{d}}$ is collision diameter in $\mathrm{cm} ; \mu$ is reduced molar mass in
$\mathrm{g}-\mathrm{mol}^{-1}, \mu=\left(\frac{1}{\mathrm{M}_{\mathrm{A}}}+\frac{1}{\mathrm{M}_{\mathrm{B}}}\right)^{-1} ; T$ is temperature in Kelvin; $\mathrm{N}_{\mathrm{A}}$ is Avogadro's number 6.022 $\times 10^{23} \mathrm{~mol}^{-1} ; \mathrm{R}$ is gas constant $6.2326 \times 10^{4} \mathrm{~cm}^{3}-$ Torr- $\mathrm{K}^{-1}-\mathrm{mol}^{-1} ; k_{\mathrm{B}}$ is Bolzmann constant $1.3805 \times 10^{-16} \mathrm{erg}-\mathrm{K}^{-1}$.

A major achievement of Lindemann's theory is its ability to explain the experimental finding that the unimolecular dissociation rate can be pressure dependent. However, it predicts the fall-off in $\mathrm{k}_{\text {uni }}$ to occur at much higher pressure than what is observed experimentally. In 1926 Hinshelwood $^{9}$ proposed that the internal degree of freedom can contribute to the threshold energy $E_{0}$. The probability that a molecule contains energy great than or equal to $E_{0}$ increases with the number of internal degree of freedom, and such the energization rate constant $k_{1}$ is larger for a complex reactant than for a simple one. Hinshelwood increases $k_{1}$ by using a much higher probability of a molecule possessing total energy $\geq E_{0}$ in s classical degrees of freedom, $\left(E_{0} / k_{\mathrm{B}} \mathrm{T}\right)^{s-1} \exp (-$ $\left.E_{0} / k_{\mathrm{B}} \mathrm{T}\right) /(\mathrm{s}-1)!$, rather than the $\operatorname{simpler} \exp \left(-E_{0} / k_{\mathrm{B}} T\right)$ that Lindemann used. The result is

$$
k_{l}=\frac{Z_{l}}{(\mathrm{~s}-1)!}\left(\frac{E_{0}}{k_{B} T}\right)^{\mathrm{s}-1} \exp \left(\frac{-E_{0}}{k_{B} T}\right)
$$

Based on the Lindemann's suggestion that $k_{1}$ could be increased by assuming that the required energy for energized molecules could be drawn in part from the internal degrees of freedom (mainly vibration) of the reactant molecule. Since $k_{1}$ increases with s classical degrees of freedom in the Lindemann-Hinshelwood theory, then $k_{2}=k_{\infty} k_{-1} / k_{1}$ should decrease with $s$. Thus the lifetime of the energized molecule $t \approx 1 / k_{2}$ increases when the molecule can store energy among a large number of degrees of freedom. Then $k_{2}$ is
expected to depend on the energy of $\mathrm{A}^{*}$. Making $k_{2}$ energy-dependent, expressed as $k(\mathrm{E})$, the energy interval from $E$ to $E+d E$ is considered:

$$
\begin{aligned}
& \mathrm{A}+\mathrm{M} \xrightarrow{d k 1} \mathrm{~A}^{*}(\mathrm{E}, \mathrm{E}+\mathrm{dE})+\mathrm{M} \\
& \mathrm{~A}^{*}(\mathrm{E}, \mathrm{E}+\mathrm{dE})+\mathrm{M} \xrightarrow{k-1} \mathrm{~A}+\mathrm{M} \\
& \mathrm{~A}^{*}(\mathrm{E}, \mathrm{E}+\mathrm{dE}) \xrightarrow{k(\mathrm{E})} \text { Products }
\end{aligned}
$$

Applying the steady-state approximation to energized intermediate $A^{*}(E, E+d E)$ leads to the differential unimolecular rate constant:

$$
d k_{\mathrm{uni}}(\mathrm{E}, \mathrm{E}+\mathrm{dE})=\frac{\mathrm{k}(\mathrm{E})\left(\mathrm{dk}_{1} / \mathrm{k}_{-1}\right)}{1+\mathrm{k}(\mathrm{E}) / \mathrm{k}_{-1}[\mathrm{M}]}
$$

It is assumed that for all pressure $\mathrm{d} k_{1} / k_{-1}$ represents the equilibrium probability and that the $A^{*}$ has energy between $E$ and $E+d E$. This probability may be denoted $P(\mathrm{E}) \mathrm{dE}$. Also $k_{-1}[\mathrm{M}]$ is the collision frequency $\omega$ between an $\mathrm{A}^{*}$ molecular and collider M, this leads to the thermal unimolecular rate constant:

$$
\mathrm{k}_{\mathrm{uni}}=\omega \int_{k_{0}}^{\infty} \frac{k(E) P(E) d E}{k(E)+\omega}
$$

In order to make accurate quantitative predictions of the fall-off behavior of a unimolecular reaction, it is essential to take into account the energy dependence of the rate constant $k(\mathrm{E})$ for the conversion of energized molecules into activated complexes where products result from decomposition or reaction of the energized complex.

Two different approaches may be taken to determine $k(\mathrm{E})$. One is to consider the explicit nature of the intramolecular motion of highly energized molecules, such as Slater theory. The other approach is based on statistical assumptions, such as RRK theory and its extension, RRKM theory. Most modern theories of unimolecular reaction rates,
including the Slater theory, the RRK theory and the RRKM theory, are based on the fundamental Lindemann mechanism involving collision energy transfer of the reactant molecules, and more specifically on Hinshelwood's development.

### 1.3.2 RRK Theory of Unimolecular Reactions

The RRK theory was developed independently and nearly simultaneously by Rice and Ramsperger ${ }^{10}$ and by Kassel. ${ }^{11}$ in 1927 and 1928. Both Rice and Ramsperger theory and Kassel theory consider that a critical energy $\mathrm{E}_{0}$ must become concentrated in one part (a specific vibration) of the molecule for reaction to occur. They used the basic LindemannHinshelwood mechanism of collision energy transfer and de-energization, but assumed more realistically that the rate constant for conversion of an energized molecule into products is proportional to a specific probability. This is a finite statistical probability that energy, $E_{0}$, is found in the relevant part of the energized molecule which contains total energy, $E$, is greater than $E_{0}$ since $E$ of the molecule under consideration is assumed to be rapidly redistributed around the molecule. This probability will increase with E and make $k(\mathrm{E})$ a function of its energy content.

The difference between the Rice and Ramsperger model and Kassel model is twofold. First, Rice and Ramsperger used classical statistical mechanics throughout, while Kassel used classical methods and also developed a quantum treatment. The quantum method turns out to be much more realistic and accurate. Second, different assumptions were made about the part of the molecule into which the critical energy $\mathrm{E}_{0}$ has to be concentrated. The Kassel's model seems slightly more realistic by assuming the energy had to be concentrated into one oscillator. The quantum version of the Kassel theory serves as a theoretical basis for the most of calculations performed in this thesis.

The classical RRK theory is based on the notion that the probability that a molecule of $s$ classical oscillators with total energy $E$ has energy greater than $E_{0}$ in one chosen oscillator, which is the critical mode leading to reaction. The assumptions used to derive the quantum RRK rate constant are similar to those for classical theory. In the single frequency quantum Kassel theory it is assumed there are s identical oscillators in the molecule, all having frequency $v$. The energized molecule has total n quanta, so $\mathrm{E}=$ $\mathrm{nh} \nu$. The critical oscillator must have m quanta for dissociation to occur, $\mathrm{m}=\mathrm{E}_{0} / \mathrm{h} \nu$.

The probability that one oscillator contains at least $m$ quanta (probability of energy $\geq m$ quanta in one chosen oscillator) from probability theory ${ }^{12}$ is

$$
\text { Probability }=\frac{n!(n-m+s-1)!}{(n-m)!(n+s-1)!}
$$

Hence, rate constant $k_{\mathrm{a}}(\mathrm{E})$ for conversion of energized molecules to product is

$$
k_{\mathrm{a}}(n h v)=\mathrm{A} \frac{\mathrm{n}!(\mathrm{n}-\mathrm{m}+\mathrm{s}-1)!}{(\mathrm{n}-\mathrm{m})!(\mathrm{n}+\mathrm{s}-1)!}
$$

where A is Arrhenius pre-exponential parameter. The corresponding $k_{1}(E)$ of the Hinshelwood expression is now derived. It refers to energy transfer into a specific quantum state rather than into an energy range $E$ to $E+d E$, as

$$
k_{1}(n h v)=k_{2} \alpha^{n}(1-\alpha)^{\mathrm{S}} \frac{(\mathrm{n}+\mathrm{s}-1)!}{\mathrm{n}!(\mathrm{s}-1)!}
$$

where $\alpha=\exp \left(-\mathrm{h} v / k_{\mathrm{B}} \mathrm{T}\right)$. Both classical and quantum versions of RRK theory were developed, and in the limit of a large excitation energy $E$ the two versions become identical.

In RRK theory the assumption is made that the rate of conversion of energized molecules into products is related to the probability that the critical energy $\mathrm{E}_{0}$ is
concentrated in one part of the molecule, e.g. in one oscillator (Kassel theory) or in one squared term (Rice-Ramsperger theory). This probability is a function of the total energy E of the energized molecule, and the total vibrations among which the vibration energy quanta can be distributed.

### 1.3.3 RRKM Theory of Unimolecular Reactions

The RRKM theory was developed using the RRK model and was extended to consider explicit vibration and rotational energies and also include zero point energies. ${ }^{13}$ Several minor modifications of the theory have been made, primarily as a result of improved treatments of external degrees of freedom. ${ }^{14,15}$

RRKM theory is a microcanonical transition state theory, and it provides the connection between statistical unimolecular rate theory and the transition state theory of thermal chemical reaction rates. Isomerization or dissociation of an energized molecule $A^{*}$ is assumed to occur via the mechanism

$$
\mathrm{A}^{*} \xrightarrow{k(E)} \mathrm{A}^{\neq} \rightarrow \text { Products }
$$

where $A^{*}$ is the transition state. The energized molecule $A^{*}$ contains both vibrational and external rotational energies by $E_{v}$ and $E_{r}$, respectively. The sum of $E_{v}$ and $E_{r}$ is $E$. To treat the external rotational energy of a nonlinear molecule quantum mechanically, the specific rotational energy levels must be considered. The RRKM rate constant $k_{E J}$ is the microcanonical transition state theory rate constant, and is given by

$$
k_{E J}=\frac{N_{E J}^{\dagger}}{h \rho_{E J}}
$$

where $N_{\mathrm{EJ}}$ is the sum of states for the active degrees of freedom in the transition states and $\rho_{E J}$ is the density of states for the active degrees of freedom in the reactants. To
determine an RRKM rate constant requires evaluating the sum of states for the transition state and the density of states for the reactants. The information needed for calculating the sum and density of states includes the total reactant energy $E$, rotational energy $E_{r}$, the unimolecular threshold $E_{0}$. One also needs harmonic vibrational frequencies and moments of inertia for both the reactant and the transition states. This information can be obtained by either experimental data or ab initio calculations.

Different experimental techniques, including static pyrolysis, carrier (flow) techniques, shock tube methods, and very-low-pressure-pyrolysis, have been used to measure $\mathrm{k}_{\text {uni }}$ as a function of temperature and pressure. One of the most significant achievements of RRKM theory is its ability to match measurements of $\mathrm{k}_{\text {uni }}$ with pressure.

### 1.3.4 Chemical Activation Reactions

The energization methods other than by molecular collision, such as photoactivation and chemical activation, may produce a non-equilibrium situation in which molecules acquire energies far in excess of the average thermal energy. This presence of excess energy in the energized adduct makes chemical activation reactions much more important in these systems. A treatment for the rate of conversion, which includes decomposition of energized adduct to product(s) (including reverse back to reactants) and the competing rate of its collision stabilization, is needed.

An example of a chemically activated reaction system is neopentyl radical $\left(\mathrm{C}_{3} \mathrm{CC} \bullet\right)+\mathrm{O}_{2}$ system. As is discussed in Chapter $3, \mathrm{C}_{3} \mathrm{CC} \bullet$ radical reacts with $\mathrm{O}_{2}$ to form a chemically activated, energized adduct $\left[\mathrm{C}_{3} \mathrm{CCOO} \bullet\right]^{*}$, this process of forming adduct is much more efficient than that by thermal molecular collision, and adduct contains excess energy from the new bond formed in this chemical reaction. The energized adduct
$\left[\mathrm{C}_{3} \mathrm{CCOO} \bullet\right]^{*}$ could go back to reactant $\mathrm{C}_{3} \mathrm{CC} \bullet+\mathrm{O}_{2}$, or could go to products $3,3-$ dimethyloxetane +OH via an intramolecular H shift. The QRRK analysis $(\mathrm{A}+\mathrm{BC} \rightarrow$ $A B C^{*}$ ) shows that the chemical activation process is more important than thermal dissociation process.

The basic idea of the treatment of a chemical activation system is that a vibration excited molecule $A B C^{*}$ formed by an association of reactants can reform reactants $A+$ BC with a rate constant $k^{\prime}(\mathrm{E})$, form decomposition products, $\mathrm{AB}+\mathrm{C}$, with a rate constant $k_{\mathrm{a}}(\mathrm{E})$ or be de-energized to stable molecules ABC .

In the strong collision assumption the first order rate constant for de-energization is equal to the collision frequency, $\omega=\mathrm{Zp}$ where p is the total pressure and Z is collision number. This assumes that stabilization occurs at energy collision.

Suppose that the fraction of molecules which are energized per unit time into the energy range between $E$ and $E+d E$ is $f(E) d E$. To simplify, one can consider decomposition path (back to reactant, $\mathrm{A}+\mathrm{BC}$, as the decomposition path), then the fraction of $\mathrm{ABC}^{*}$ decomposing (path $\mathrm{A}+\mathrm{BC}$ ) compared with those stabilized (path $\mathrm{ABC})$ is $\mathrm{k}(\mathrm{E}) /[\mathrm{k}(\mathrm{E})+\omega]$. The fraction of molecules in the energy range between E and $E+d E$ decomposing to products is therefore $\{k(E) /[k(E)+\omega]\} f(E) d E$, and the total number of molecules decomposing per unit time (D), at all energies above the critical energy $\mathrm{E}_{0}$, is: ${ }^{16}$

$$
\mathrm{D}=\int_{0_{0}}^{\infty} \frac{\mathrm{k}(E)}{\mathrm{k}(E)+\omega} \mathrm{f}(E) \mathrm{dE}
$$

Corresponding, the total rate of stabilization (S) is:

$$
\mathrm{S}=\int_{E_{0}}^{\infty} \frac{\omega}{\mathrm{k}(E)+\omega} \mathrm{f}(E) \mathrm{dE}
$$

Considering an average rate constant $<\mathrm{k}>$ for all energies above $\mathrm{E}_{0}$, one would have:

$$
\frac{\langle\mathrm{k}\rangle}{\omega}=\frac{\mathrm{D}}{\mathrm{~S}}=\frac{\text { No. molecules decomposing per unit time }}{\text { No. of molecules being stabilized per unit time }}
$$

So,

$$
<\mathrm{k}>=\omega \frac{\int_{=0}^{\omega}\{\mathrm{k}(E) /[\mathrm{k}(E)+\omega]\} f(E) \mathrm{dE}}{\int_{E_{0}}^{\infty}\{\omega /[\mathrm{k}(E)+\omega]\} f(E) \mathrm{dE}}
$$

The $f(E)$ is the distribution function of energized molecules in the energy range between E and $\mathrm{E}+\mathrm{dE}$. In the thermal energy transfer systems, this distribution function is simply the thermal quantum Boltzmann distribution $K(E)$ and the rate of energy transfer into the energy range between E and $\mathrm{E}+\mathrm{dE}$ is $\mathrm{K}(E) \mathrm{dE}=\mathrm{d} k_{1} / k_{2}$. For the chemically activated system described here, the distribution function can be derived by applying the principle of detailed balancing to the reverse process to reactants. Consider a situation in which other processes can be ignored and equilibrium is established between $A^{*}$ and reactants. Then the fraction of molecules with energy between $E$ and $E+d E$ is Boltzmann distribution $\mathrm{K}(E) \mathrm{dE}$, so the rate of dissociation to reactants is then $\mathrm{k}^{\prime}(E) \mathrm{K}(E) \mathrm{dE}$, and by the principle of detailed balancing this also gives the rate of combination of reactants to give $A^{*}$ in this energy range. The total rate of energy transfer to all levels above the minimum energy $E_{\text {min }}$ (the minimum energy of $A^{*}$ ) is:

$$
\text { Total rate of energization }=\int_{=0}^{\infty} \mathrm{k}^{\prime}(E) \mathrm{K}(E) \mathrm{dE}
$$

Therefore, the distribution function is given by:

$$
f(E) \delta \mathrm{E}=\frac{\mathrm{k}^{\prime}(E) \mathrm{K}(E) \mathrm{dE}}{\int_{\mathbb{E}_{0}^{\infty}}^{\infty} \mathrm{k}^{\prime}(E) \mathrm{K}(E) \mathrm{dE}}
$$

The $f(E) \mathrm{dE}$ can be incorporated into QRRK theory for $\mathrm{k}(E)$ and $\mathrm{k}_{1}(E)$ serves as a basis for the calculations for chemical activation reaction systems.

### 1.3.5 QRRK Analysis for Chemical Activation and Unimolecular Dissociation

1.3.5.1 Input Information Requirements for QRRK Calculation. Quantum Rice-Ramsperger-Kassel (QRRK) analysis, as initially presented by Dean ${ }^{17-19}$ combined with the modified strong collision approach of Gilbert et al., ${ }^{20,21}$ to compute rate constants for both chemical activation and unimolecular reactions, over a range of temperature and pressure. The computer program CHEMDIS is designed to calculate unimolecular and chemical activation reactions based on the QRRK theory and unimolecular dissociation and chemical activation formalism. The input parameters for CHEMDIS are: (1) Highpressure limit rate constants (Arrhenius A factor and activation energy $\mathrm{E}_{\mathrm{a}}$ ) for each reaction included for analysis; (2) A reduced set of three vibration frequencies and their associated degeneracy; (3) Lennard-Jones transport parameters, (s (Angstroms) and e/k (Kelvin)), and (4) molecular weight of well species.

High pressure limit rate constants $k_{\infty}$ 's are fitted by three parameters $\mathrm{A}_{\infty}, \mathrm{n}$, and $E_{a}$ over temperature range from 298 to $2000 \mathrm{~K}, k_{\infty}=\mathrm{A}_{\infty}(\mathrm{T})^{\mathrm{n}} \exp \left(-E_{a} / \mathrm{R} T\right)$. Entropy differences between reactant and transition state are used to determine the pre-exponential factor, A , via canonical Transition State Theory (TST):

$$
\mathrm{A}=\left(k_{\mathrm{B}} T / h_{p}\right) \exp \left(\Delta S^{\not} / \mathrm{R}\right), \quad E_{a}=\Delta H^{\neq}
$$

where $h_{p}$ is the Planck constant and $\mathrm{k}_{\mathrm{B}}$ is the Boltzmann constant. $\Delta \mathrm{S}^{\neq}=\mathrm{S}(\mathrm{TST})-$ S (reactants) and $\Delta \mathrm{H}^{\neq}=\mathrm{H}(\mathrm{TST})-\mathrm{H}$ (reactants). Treatment of the internal rotors for $S$ and $C_{p}(T)$ of reactants and the TST's is important here because these internal rotors are often lost in the cyclic transition state structures. Pre-exponential factors $\left(\mathrm{A}_{\infty}\right)$, are calculated
from structures determined by DFT or estimated from the literature and from trends in homologous series of reactions. Activation energies come from ab initio calculations plus evaluated endothermicity of reaction $\Delta \mathrm{U}_{\mathrm{rxn}}$, and from analogy to similar reactions with known energies.

Reduced sets of three vibration frequencies and their associated degeneracies are computed from fits to heat capacity data, as described by Ritter and Bozzelli et al. ${ }^{22,23}$ These have been shown by Ritter to accurately reproduce molecular heat capacities, $C p(T)$, and by Bozzelli et al. ${ }^{23}$ to yield accurate ratios of density of states to partition coefficient, $\rho(E) / Q$.

Lennard-Jones parameters, sigma (angstroms) and $\varepsilon / \mathrm{k}$ (Kelvin's), are obtained from tabulations ${ }^{24}$ and from a calculation method based on molar volumes and compressibility. ${ }^{25}$

### 1.3.5.2 Quantum RRK / Master Equation Calculation. The Quantum RRK / Master

 equation analysis is described by Chang et al. ${ }^{17,26}$ The QRRK code utilizes a reduced set of three vibration frequencies which accurately reproduce the molecule's (adduct) heat capacity; the code includes contribution from one external rotation in calculation of the ratio of the density of states to the partition coefficient $\rho(\mathrm{E}) / \mathrm{Q}$.Comparisons of ratios of these $\rho(E) / Q$ with direct count $\rho(E) / Q$ 's are shown to be in good agreement. ${ }^{23}$ Rate constant results from the QRRK/Master equation analysis are shown to accurately reproduce experimental data on several complex systems. They also provide a reasonable method to estimate rate constants for numerical integration codes by which the effects of temperature and pressure can be evaluated in complex reaction systems.

Multifrequency QRRK analysis is used to calculate $k(\mathrm{E})$ with a master equation analysis $^{26}$ for fall-off. A 500 cal . energy grain interval is used for the energy intervals. Rate constants are obtained as a function of temperature and pressure for the chemical activation and dissociation reactions. The master equation analysis ${ }^{26}$ uses an exponentialdown model for the energy transfer function. Troe et al. ${ }^{27}$ reported that $(\Delta E)^{\circ}{ }_{\text {down }}$ is independent of temperature $(293-866 \mathrm{~K})$ for the rare and diatomic bath gases, and Hann et al. ${ }^{28}$ recently determined a value of $(\Delta E)^{\circ}{ }_{\text {down }}=500 \mathrm{~cm}^{-1}$ for matching the twodimensional master equation solutions to the experimental fall-off behavior in the $\mathrm{C}_{3} \mathrm{H}_{3}+$ $\mathrm{O}_{2}$ system with $\mathrm{N}_{2}$ bath gas. Knyazev and Slagle ${ }^{29}$ reported that $(\Delta E)^{\circ}{ }_{\text {down }}$ changes with temperature; they compared three models, two of which are $(\Delta E)^{\circ}{ }_{\text {down }}=\alpha \mathrm{T}$ and $(\Delta E)^{\circ}{ }_{\text {down }}$ $=$ constant, in reaction of $n-\mathrm{C}_{4} \mathrm{H}_{9} \Leftrightarrow \mathrm{C}_{2} \mathrm{H}_{5}+\mathrm{C}_{2} \mathrm{H}_{4}$ with Helium as bath gas. The energy difference between the values of the barrier height needed to fit the experimental data with these two $(\Delta E)^{\circ}{ }_{\text {down }}$ models is only $0.4 \mathrm{~kJ} \mathrm{~mol}^{-1}$ over a relatively narrow temperature range $(560-620 \mathrm{~K})$. Constant values of $1000 \mathrm{cal} \mathrm{mol}^{-1}\left(\mathrm{~N}_{2}\right.$ as bath gas) and $570 \mathrm{cal} \mathrm{mol}^{-1}$ (He as bath gas) for $(\Delta E)^{\circ}{ }_{\text {down }}$ are used in this study.

## CHAPTER 2

## THERMOCHEMICAL PROPERTIES OF CHLORINATED ALCOHOLS, HYDROPEROXIDES AND CORRESPONDING RADICALS

### 2.1 Background

The incineration and atmospheric oxidation processes of chlorine-containing organic compounds are of major interest since such compounds can contribute to the transport of chlorine species to atmosphere and stratosphere. The oxidation of chlorinated hydrocarbon is initiated mainly by the reaction with OH radical to produce chloroalkyl radicals that will react with $\mathrm{O}_{2}$ to generate peroxy radicals. Chlorinated alkyl peroxy species are also formed in the atmosphere where chlorine atom can add to olefins and then react with $\mathrm{O}_{2}$. Chloro-alkyl hydroperoxides are produced in the further reactions of alkylperoxy radicals with the hydroperoxy radical, $\mathrm{HO}_{2}$, and are also formed via H -atom abstraction from other hydrocarbon species with weakly bonded hydrogen atoms. Chloroalkyl peroxy radicals are important intermediates in low-temperature oxidation such as in the initial stages of combustion and in the atmospheric photochemical oxidation of chlorohydrocarbons because peroxy radical reactions are the first step in the oxidation processes, these radicals will subsequently react with NO or another organic peroxy radical to form the corresponding chlorinated alkoxy radicals. ${ }^{30}$ The thermochemistry of the dissociation products of chlorinated alcohols and alkyl hydroperoxides are needed for understanding and predicting the reaction pathways, rate constants and equilibrium constants in order to assess the impact of chlorocarbon degradation products on the environment. Reliable thermochemical properties of these oxygenated chlorocarbon species are important in evaluation of kinetics or
thermodynamic equilibrium for both destruction and synthesis processes and in chemical engineering design.

### 2.2 Calculation Method

### 2.2.1 Computational Details

All of the density functional and $a b$ initio calculations are performed using the Gaussian 94/98 program. ${ }^{31,32}$ The geometry optimization, harmonic vibration frequencies and zeropoint vibrational energies (ZPVE) are computed at the B3LYP/6-31G(d,p) level. Three calculation methods are proposed obtain single point total electronic energies:

1. B3LYP/6-311+G(3df,2p)
2. $\operatorname{QCISD}(\mathrm{T}) / 6-31 \mathrm{G}(\mathrm{d}, \mathrm{p})$
3. $\mathrm{CBSQ} / / \mathrm{B} 3 \mathrm{LYP} / 6-31 \mathrm{G}(\mathrm{d}, \mathrm{p})$

The DFT method computes electron correlation via general functionals of the electron density. The best DFT methods achieve significantly greater accuracy than Hartree-Fock theory at only a modest increase in cost, and this is achieved by including some of the effects of electron correlation much less expensively than traditional correlated methods. ${ }^{1}$ The B3LYP with the basis set of $6-31 \mathrm{G}(\mathrm{d}, \mathrm{p})$ is used for geometry optimization and frequency calculation. Curtiss et al. ${ }^{33}$ reported that B3LYP/6-31G(d,p) provides highly accurate structures for compounds with elements up to atomic number ten. Durant ${ }^{34,35}$ has compared density functional calculations B3LYP and hybrid (BH and H) with MP2 and Hartree-Fock methods for geometry and vibration frequencies. He reports that these density functional methods provide excellent geometries and vibration frequencies, relative to MP2 at a reduced computational expense. Petersson et al. ${ }^{36}$
recommended use of B3LYP for geometry and frequencies in several of his CBS calculation methods. B3LYP/6-311+G(3df,2p) is chosen to see if this larger basis set with diffuse functions results in any improvement to the above commonly used density functional calculation method. ${ }^{37} \mathrm{QCISD}(\mathrm{T}) / 6-31 \mathrm{G}(\mathrm{d}, \mathrm{p})$ is a configuration interaction method; but with a small, economical basis set. ${ }^{38,39}$ CBS-Q calculation is a high level composite method with an empirical correction reported compared with $\mathrm{QCISD}(\mathrm{T}) / 6$ $311+\mathrm{G}(3 \mathrm{df}, 2 \mathrm{p}){ }^{40,41}$ CBS-Q ${ }^{6}$ attempts to approximate the energy of a species at the infinite basis set limit by an extrapolation of the energies of pair natural orbital at the MP2 level. The effects of going from MP2 to $\operatorname{QCISD}(T)$ are accounted for with an additivity scheme. The geometry is obtained at the MP2/6-31G level of theory, while the ZPE used is the scaled (by 0.9135 ) HF/6-31G value. For the open-shell systems, there is also a correction for spin contamination in the unrestricted Hartree-Fock wave function. The CBS-Q method has been shown to yield reliable $\Delta H_{\mathrm{f}}{ }^{0} 298$ values for small molecules. ${ }^{6}$ The CBSQ//B3LYP/6-31G(d,p) method differs from CBS-Q in that it employs improved geometry and ZPE at the B3LYP/6-31G(d,p) level with a correction for spin contamination for the open shell systems.

### 2.2.2 Enthalpies of Formation $\left(\Delta H_{f}{ }^{\mathbf{0}}{ }_{298}\right)$

The $\Delta H_{\mathrm{f}}{ }^{\mathrm{o}} 298$ are calculated using total energies and isodesmic reactions. Total energies are corrected by ZPVE, which are scaled by 0.9806 as recommended by Scott et al. ${ }^{42}$ Thermal correction is taken into account using the B3LYP structure and vibrations. Isodesmic reactions are hypothetical reactions where the number of electron pairs and the bonds of the same type are conserved on both sides of the equation, only the relationship among the bonds are altered. Density functional and ab initio calculations with ZPVE and
thermal correction are performed for all four compounds in each reaction, and enthalpy of reaction $\Delta H^{\circ}{ }_{\mathrm{rxn}, 298}$ is calculated. Since the enthalpies of formation of the three compounds, have been experimentally determined or theoretically calculated, the unknown enthalpy of the target compound is obtained.

Density functional and $a b$ initio calculations at the B3LYP/6-31G(d,p), B3LYP/6$311+\mathrm{G}(3 \mathrm{df}, 2 \mathrm{p}), \operatorname{QCISD}(\mathrm{T}) / 6-31 \mathrm{G}(\mathrm{d}, \mathrm{p})$ and CBS-Q level of theory are performed on the most stable conformer of each compound, and the $\Delta H_{f}^{0} 298$ of this conformer is calculated using isodesmic reactions. $\Delta H_{\mathrm{f}}^{\mathrm{o}} 2988^{\prime} \mathrm{s}$ of other conformers, if present, are estimated with the same method. Final $\Delta H_{\mathrm{f}}^{\mathrm{o}} 298$ values are calculated from a statistical distribution of rotational conformers.

### 2.2.3 Entropy and Heat Capacities

Contributions of vibration, translation, and external rotation to entropies and heat capacities are calculated from scaled vibrational frequencies and moments of inertia of the DFT optimized structures. Contributions from hindered rotors to $S_{298}^{0}$ and $C_{p}(T)$ 's are determined using direct integration over energy levels of the intramolecular rotational potential curves, which can be represented by a truncated Fourier series expansion. ${ }^{43}$ Potential barriers for internal rotations are determined at the B3LYP/6-31G(d,p) calculation level. A technique for calculation of thermodynamic functions from hindered rotations with arbitrary potentials is used to calculate hindered internal contributions to $S^{0}{ }_{298}$ and $C_{p}(T)$ 's. ${ }^{43}$ This technique employs expansion of the hindrance potential in the Fourier series, calculation of the Hamiltonian matrix in the basis of wave functions of free internal rotation, and subsequent calculation of energy levels by direct diagonalization of the Hamiltonian matrix. The calculations are based on optimized
geometries, atom connectivity, and the coefficients of the Fourier expansion components from rotational potential curves. The torsional potential calculated at the discrete torsional angles is represented by a truncated Fourier series.

$$
\mathrm{V}(\Phi)=\mathrm{a}_{0}+\sum \mathrm{a}_{\mathrm{i}} \cos (\mathrm{i} \Phi)+\sum \mathrm{b}_{\mathrm{i}} \sin (\mathrm{i} \Phi) \quad \mathrm{i}=1,2,3,4,5
$$

Values of the coefficients $a_{i}$ and $b_{i}$ are calculated to provide the minimum and maxima of the torsional potentials with allowance of a shift of the theoretical extreme angular positions.

## $2.3 \alpha$-Chlorinated Ethanols and Radicals

### 2.3.1 Geometries

The lowest energy conformation for the two chloroethanols and three hydroxyl chloroethyl radicals consistently has the hydroxyl H atom gauche to the maximum number of chlorine atoms as illustrated in the Appendix Table A.1, despite an apparent steric penalty. These lowest energy conformations exhibit the anomeric effect as those of chloromethanols reported by Schneider ${ }^{44}$, Omoto ${ }^{45}$ and Sun et al. ${ }^{46}$ This preference is ascribed to the delocalization of the lone pair $\mathrm{e}^{-}$on the oxygen with the antibonding $\sigma^{*}$ orbital of the $\mathrm{C}-\mathrm{Cl}$ bond; it is also supported by the electrostatic repulsion between the non-bonding $\mathrm{e}^{-}$pair of oxygen and electronegative Cl atom(s) and intramolecular interaction between the hydroxyl H atom and the Cl atom. ${ }^{47}$

It can be seen from Table A. 1 that the $\mathrm{C}-\mathrm{O}$ bond length decreases significantly with chlorine substitution. This is due to the anomeric effect where the non-bonding $\mathrm{e}^{-}$ pair on oxygen is mixing with the antibonding orbital of the $\mathrm{C}-\mathrm{Cl}$ bond. ${ }^{44,45,48}$ In valence bond terminology, this would be described as:

The anomeric effect can also be seen in the $\mathrm{C}-\mathrm{Cl}$ bond length, which is longer than normal $\mathrm{C}-\mathrm{Cl}$ bond. The $\mathrm{O}-\mathrm{H}$ bond increases with increased chlorine substitution and bond strength gets stronger (see the bond energy discussion below).

The Density Functional structure predicts, planar $\left(s p^{2}\right)$ vs tetrahedral $\left(s p^{3}\right)$, on the hydroxyethyl and hydroxychloroethyl radicals. The $\angle \mathrm{H}_{\mathrm{c}}-\mathrm{C}-\mathrm{C}-\mathrm{H}_{\mathrm{c}}$ dihedral angle in $\mathrm{C}^{\circ} \mathrm{H}_{2} \mathrm{CH}_{2} \mathrm{OH}$ and $\mathrm{C}^{\bullet} \mathrm{H}_{2} \mathrm{CHClOH}$ are $170.1^{\circ}$ and $168.0^{\circ}$, which suggests a non-planar structure. However, the $\angle \mathrm{H}_{\mathrm{c}}-\mathrm{C}-\mathrm{C}-\mathrm{H}_{\mathrm{c}}$ and the $\angle \mathrm{C}-\mathrm{C}-\mathrm{O}-\mathrm{H}$ dihedral angle in $\mathrm{C}^{\circ} \mathrm{H}_{2} \mathrm{CCl}_{2} \mathrm{OH}$ both are $180.0^{\circ}$, indicating there is a mirror plane between the two chlorine atoms, i.e. $C_{s}$ symmetry in $\mathrm{C}^{\bullet} \mathrm{H}_{2} \mathrm{CCl}_{2} \mathrm{OH}$. The inversion frequencies for $\mathrm{C}^{\bullet} \mathrm{H}_{2} \mathrm{CH}_{2} \mathrm{OH}, \mathrm{C}^{\bullet} \mathrm{H}_{2} \mathrm{CHClOH}$ and $\mathrm{C}^{\bullet} \mathrm{H}_{2} \mathrm{CCl}_{2} \mathrm{OH}$ are calculated in this work to be $458.2,666.5$ and $539.2 \mathrm{~cm}^{-1}$, respectively. The symmetry number is assigned as 1 for $\mathrm{C}^{\bullet} \mathrm{H}_{2} \mathrm{CH}_{2} \mathrm{OH}$ and $\mathrm{C}^{\bullet} \mathrm{H}_{2} \mathrm{CHClOH}$, and two for $\mathrm{C}^{\bullet} \mathrm{H}_{2} \mathrm{CCl}_{2} \mathrm{OH}$ on the basis of these data.

### 2.3.2 Rotational Barriers

Potential barriers for internal rotations of all the species are calculated at the B3LYP/6$31 \mathrm{G}(\mathrm{d}, \mathrm{p})$ level. Potential energy as function of dihedral angle is determined by scanning the torsion angles from $0^{\circ}$ to $360^{\circ}$ at $15^{\circ}$ intervals and allowing the remaining molecular structural parameters to be optimized. Each minimum and maximum on the torsional potential are fully optimized. The barriers for internal rotations are calculated from the differences between the total energy of each conformation and that of the most stable conformer.

The calculated rotational barriers about the $\mathrm{C}-\mathrm{C}$ bond of $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}$, $\mathrm{CH}_{3} \mathrm{CHClOH}, \mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{OH}, \mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{O}^{\bullet}, \mathrm{CH}_{3} \mathrm{CHClO}^{\bullet}, \mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{O}^{\bullet}, \mathrm{CH}_{3} \mathrm{C}^{\bullet} \mathrm{HOH}$ and $\mathrm{CH}_{3} \mathrm{C}^{\bullet} \mathrm{ClOH}$ are shown in Figure 2.1.

Figure 2.1 Potential barriers for internal rotation about the $\mathrm{C}-\mathrm{C}$ bond of $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$, $\mathrm{CH}_{3} \mathrm{CHClOH}, \mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{OH}, \mathrm{C}_{2} \mathrm{H}_{5} \mathrm{O}^{\bullet}, \mathrm{CH}_{3} \mathrm{CHClO}^{\bullet}, \mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{O}^{\bullet}, \mathrm{CH}_{3} \mathrm{C}^{\bullet} \mathrm{HOH}$, and $\mathrm{CH}_{3} \mathrm{C}^{\bullet} \mathrm{ClOH}$.

All the curves for $\mathrm{C}-\mathrm{C}$ torsion potential are symmetric and show a threefold barrier except $\mathrm{CH}_{3} \mathrm{C}^{\bullet} \mathrm{HOH}$, which shows a sixfold barrier. The barrier heights for $\mathrm{C}-\mathrm{C}$ torsion are: $3.62,3.61,4.91 \mathrm{kcal} / \mathrm{mol}$ for $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}, \mathrm{CH}_{3} \mathrm{CHClOH}, \mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{OH} ; 2.49$, $3.41,3.71 \mathrm{kcal} / \mathrm{mol}$ for $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{O}^{\bullet}, \mathrm{CH}_{3} \mathrm{CHClO}^{\bullet}, \mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{O}^{\bullet} ; 1.82$, and $2.13 \mathrm{kcal} / \mathrm{mol}$ for $\mathrm{CH}_{3} \mathrm{C}^{\bullet} \mathrm{HOH}$ and $\mathrm{CH}_{3} \mathrm{C}^{\bullet} \mathrm{ClOH}$. The above data show the barrier for the $\mathrm{C}-\mathrm{C}$ torsion increases with increasing $\alpha$-chlorine substitution on ethanol, ethoxy, and $\alpha$-hydroxy-ethyl radical. The barriers for $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}$ vs $\mathrm{CH}_{3} \mathrm{CHClOH}$, are, however, quite similar, 3.62
and $3.61 \mathrm{kcal} / \mathrm{mol}$ at the B3LYP level. These two barriers are furture evaluated by using MP2(FULL)/6-31G(d) level calculation; the values are slightly higher, and are 4.04 and $4.28 \mathrm{kcal} / \mathrm{mol}$ respectively. The reason for the similarity in barriers for $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}$ and $\mathrm{CH}_{3} \mathrm{CHClOH}$ is likely due to the anomeric effect ${ }^{45}$ in $\mathrm{CH}_{3} \mathrm{CHClOH}$. The data also show that $\mathrm{C}-\mathrm{C}$ torsion barriers for (chloro)ethanols are higher than those of the corresponding (chloro)ethoxy radicals, which may in part be due to steric hindrance of the hydroxyl hydrogen.

Figure 2.2 Potential barriers for internal rotation about the $\mathrm{C}-\mathrm{C}$ bond of $\mathrm{C}^{\bullet} \mathrm{H}_{2} \mathrm{CH}_{2} \mathrm{OH}$, $\mathrm{C}^{\bullet} \mathrm{H}_{2} \mathrm{CHClOH}$ and $\mathrm{C}^{\bullet} \mathrm{H}_{2} \mathrm{CCl}_{2} \mathrm{OH}$.

Figure 2.2 shows the calculated rotational barriers about the $\mathrm{C}-\mathrm{C}$ bond for $\mathrm{C}^{\bullet} \mathrm{H}_{2} \mathrm{CH}_{2} \mathrm{OH}, \mathrm{C}^{\bullet} \mathrm{H}_{2} \mathrm{CHClOH}$ and $\mathrm{C}^{\bullet} \mathrm{H}_{2} \mathrm{CCl}_{2} \mathrm{OH}$. These $\mathrm{C}-\mathrm{C}$ torsion potentials show a twofold barrier for both of the chlorinated hydroxy ethyl radicals; but a fourfold barrier in
$\mathrm{C}^{\bullet} \mathrm{H}_{2} \mathrm{CH}_{2} \mathrm{OH}$. The $\mathrm{H}--\mathrm{OH}$ eclipsed conformer is the most stable for the $\mathrm{C}-\mathrm{C}$ torsion of $\mathrm{C}^{\bullet} \mathrm{H}_{2} \mathrm{CCl}_{2} \mathrm{OH}$ due to the interaction of H atom on the $-\mathrm{C}^{\bullet} \mathrm{H}_{2}$ group and the O atom (the interatomic distance $2.483 \AA$ ). In contrast, the $\mathrm{H}--\mathrm{OH}$ gauche structure (the $\angle \mathrm{H}_{\mathrm{c}}-\mathrm{C}-\mathrm{C}-\mathrm{Cl}$ dihedral $207.56^{\circ}$ ) lacks the above interaction due to a longer interatomic distance, 2.930 $\AA$. This gauche structure is $3.07 \mathrm{kcal} / \mathrm{mol}$ higher energy and corresponds to the maximum point on the potential curve. Similar maxima and minima structures exist in $\mathrm{C}^{\bullet} \mathrm{H}_{2} \mathrm{CHClOH}$ and $\mathrm{C}^{\bullet} \mathrm{H}_{2} \mathrm{CH}_{2} \mathrm{OH}$. The $\mathrm{C}-\mathrm{C}$ rotation barrier in $\mathrm{C}^{\bullet} \mathrm{H}_{2} \mathrm{CHClOH}$ calculated at the B3LYP level is $4.60 \mathrm{kcal} / \mathrm{mol}$, which is $1.53 \mathrm{kcal} / \mathrm{mol}$ higher than the barrier in $\mathrm{C}^{\bullet} \mathrm{H}_{2} \mathrm{CCl}_{2} \mathrm{OH}$. MP2/6-31G(d) calculations in this work also show a decrease in barrier in $\mathrm{C}^{\bullet} \mathrm{H}_{2} \mathrm{CCl}_{2} \mathrm{OH}$ relative to $\mathrm{C}^{\bullet} \mathrm{H}_{2} \mathrm{CHClOH}$ and they also predict partial $s p^{2}$ geometry for the $-\mathrm{CH}_{2}{ }^{\text { }}$ groups.

Figure 2.3 Potential barriers for internal rotation about the $\mathrm{C}-\mathrm{O}$ bond of $\mathrm{CH}_{3} \mathrm{CHClOH}$ and $\mathrm{C}^{\bullet} \mathrm{H}_{2} \mathrm{CHClOH}$.

The higher barrier for $\mathrm{C}^{\bullet} \mathrm{H}_{2} \mathrm{CHClOH}$ suggests that the $\mathrm{H}--\mathrm{OH}$ eclipsed conformer of $\mathrm{C}^{\bullet} \mathrm{H}_{2} \mathrm{CHClOH}$ has extra stability. This $\mathrm{C}^{\bullet} \mathrm{H}_{2} \mathrm{CCl}_{2} \mathrm{OH}$ radical exhibits hyperconjugation between the $-\mathrm{CH}_{2}{ }^{*}$ center and the $\sigma^{*}(\mathrm{C}-\mathrm{Cl})$ molecular orbital in its lowest energy conformer. ${ }^{21}$ This effective orbital overlap is possible because the dihedral $\angle \mathrm{H}_{\mathrm{c}}-\mathrm{C}-\mathrm{C}-\mathrm{H}_{\mathrm{c}}$ and $\angle \mathrm{H}_{\mathrm{c}}-\mathrm{C}-\mathrm{C}-\mathrm{O}$ in the minimum energy conformer are $32.2^{\circ}$ and $-25.1^{\circ}$ respectively, so the $p$ orbital in the $-\mathrm{CH}_{2}{ }^{*}$ center and the $\sigma^{*}(\mathrm{C}-\mathrm{Cl})$ orbital are nearly parallel. This reduces the minima energy for $\mathrm{C}^{\bullet} \mathrm{H}_{2} \mathrm{CHClOH}$ and gives it a higher barrier than either the parent or $\mathrm{C}^{\bullet} \mathrm{H}_{2} \mathrm{CCl}_{2} \mathrm{OH}$.

Figure 2.4 Potential barriers for internal rotation about the $\mathrm{C}-\mathrm{O}$ bond of $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}$, $\mathrm{C}^{\bullet} \mathrm{H}_{2} \mathrm{CH}_{2} \mathrm{OH}, \mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{OH}$ and $\mathrm{C}^{\bullet} \mathrm{H}_{2} \mathrm{CCl}_{2} \mathrm{OH}$.

The calculated rotational barriers about the $\mathrm{C}-\mathrm{O}$ bond of $\mathrm{CH}_{3} \mathrm{CHClOH}$ and $\mathrm{C}^{\bullet} \mathrm{H}_{2} \mathrm{CHClOH}$ are shown in Figure 2.3. The torsion potential curves for rotation about the
$\mathrm{C}-\mathrm{O}$ bonds in $\mathrm{CH}_{3} \mathrm{CHClOH}$ and $\mathrm{C}^{\circ} \mathrm{H}_{2} \mathrm{CHClOH}$ are similar. The most stable conformer is $\mathrm{R}-\mathrm{H}\left(\mathrm{R}=\mathrm{CH}_{3}\right.$ or $\left.\mathrm{CH}_{2}\right)$ anti conformer, and its energy is lower than that of the $\mathrm{R}-\mathrm{H}$ gauche conformer. This is because an oxygen non-bonding $\mathrm{e}^{-}$pair eclipsed to the H atom on the $\alpha$-carbon in the R --H anti conformer, but eclipsed to the R group on the $\alpha$-carbon in the R --H gauche conformer. The maxima points on the potential curves correspond to the structures that the hydroxyl H atom is anti to the Cl atom on $\alpha$-carbon because the two non-bonding $\mathrm{e}^{-}$pairs from oxygen are gauche to the Cl atom. This preference can also be ascribed to anomeric effect, the delocalization of the lone pair $\mathrm{e}^{-}$on the oxygen with the antibonding $\sigma^{*}$ orbital of the $\mathrm{C}-\mathrm{Cl}$ bond. This phenomenon is similar to that in the chloromethanol, which is observed by our previous study. ${ }^{46}$

Figure 2.4 shows the calculated rotational barriers about the $\mathrm{C}-\mathrm{O}$ bond of $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}, \mathrm{C}^{*} \mathrm{H}_{2} \mathrm{CH}_{2} \mathrm{OH}, \mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{OH}$ and $\mathrm{C}^{*} \mathrm{H}_{2} \mathrm{CCl}_{2} \mathrm{OH}$. The $\mathrm{C}-\mathrm{O}$ torsion potential curves for $\mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{OH}$ and $\mathrm{C}^{\circ} \mathrm{H}_{2} \mathrm{CCl}_{2} \mathrm{OH}$ are similar and have the same maximum barrier of $5.68 \mathrm{kcal} / \mathrm{mol}$. The R--H anti structure is the stable conformation with the two non-bonding $\mathrm{e}^{-}$pairs from oxygen gauche to the two Cl atoms. The $\mathrm{R}--\mathrm{H}$ gauche conformers have higher energies than those of the R--H anti conformers because of the three gauche interactions between two non-bonding $\mathrm{e}^{-}$pairs and the Cl atom (only two of these interactions in the R--H anti conformers). The energy difference between the two conformers calculated at the CBS-Q level is: $3.27 \mathrm{kcal} / \mathrm{mol}$ for $\mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{OH}, 2.68$ $\mathrm{kcal} / \mathrm{mol}$ for $\mathrm{C}^{*} \mathrm{H}_{2} \mathrm{CCl}_{2} \mathrm{OH}$. This is in agreement with the energy difference for similar conformers in $\mathrm{CHCl}_{2} \mathrm{OH}, 2.94 \mathrm{kcal} / \mathrm{mol}$ at the same level of calculation. These values support that a gauche interaction between a Cl atom and an O atom non-bonding $\mathrm{e}^{-}$pair increases energy in the molecule by ca. $3 \mathrm{kcal} / \mathrm{mol} .^{46}$ The $\mathrm{C}-\mathrm{O}$ torsion potential for
$\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}$ and $\mathrm{C}^{\bullet} \mathrm{H}_{2} \mathrm{CH}_{2} \mathrm{OH}$ are also similar and they have lower barriers relative to $\mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{OH}$ and $\mathrm{C}^{*} \mathrm{H}_{2} \mathrm{CCl}_{2} \mathrm{OH}$.

Figure 2.5 Potential barriers for internal rotation about the $\mathrm{C}-\mathrm{O}$ bond of $\mathrm{CH}_{3} \mathrm{C}^{*} \mathrm{HOH}$ and $\mathrm{CH}_{3} \mathrm{C}^{\circ} \mathrm{ClOH}$.

The calculated rotational barriers about the $\mathrm{C}-\mathrm{O}$ bond of $\mathrm{CH}_{3} \mathrm{C}^{\bullet} \mathrm{HOH}$ and $\mathrm{CH}_{3} \mathrm{C}^{\bullet} \mathrm{ClOH}$ are shown in Figure 2.5. The $\mathrm{C}-\mathrm{O}$ torsion potential for $\mathrm{CH}_{3} \mathrm{C}^{\bullet} \mathrm{ClOH}$ has a maximum corresponding to the structure with a $\mathrm{C}-\mathrm{C}-\mathrm{O}-\mathrm{H}$ dihedral of $91.30^{\circ}$. In this structure, the two non-bonding $\mathrm{e}^{-}$pairs from the O atom are eclipsed with the Cl atom and the $-\mathrm{CH}_{3}$ group, with energy increased by $4.97 \mathrm{kcal} / \mathrm{mol}$ relative to that of the stable conformer, which has the two non-bonding e- pairs gauche to the Cl atom and methyl group. The $\mathrm{C}-\mathrm{O}$ torsion potential for $\mathrm{CH}_{3} \mathrm{C} \cdot \mathrm{HOH}$ also has a similar curve; however, the $\mathrm{CH}_{3}--\mathrm{H}$ eclipsed structure for $\mathrm{CH}_{3} \mathrm{C}^{\bullet} \mathrm{ClOH}$ has energy $3.43 \mathrm{kcal} / \mathrm{mol}$ higher than that of
$\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}$ and $\mathrm{C}^{\bullet} \mathrm{H}_{2} \mathrm{CH}_{2} \mathrm{OH}$ are also similar and they have lower barriers relative to $\mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{OH}$ and $\mathrm{C}^{*} \mathrm{H}_{2} \mathrm{CCl}_{2} \mathrm{OH}$.

Figure 2.5 Potential barriers for internal rotation about the $\mathrm{C}-\mathrm{O}$ bond of $\mathrm{CH}_{3} \mathrm{C}^{\bullet} \mathrm{HOH}$ and $\mathrm{CH}_{3} \mathrm{C}^{\bullet} \mathrm{ClOH}$.

The calculated rotational barriers about the $\mathrm{C}-\mathrm{O}$ bond of $\mathrm{CH}_{3} \mathrm{C}^{\bullet} \mathrm{HOH}$ and $\mathrm{CH}_{3} \mathrm{C}^{\bullet} \mathrm{ClOH}$ are shown in Figure 2.5. The $\mathrm{C}-\mathrm{O}$ torsion potential for $\mathrm{CH}_{3} \mathrm{C}^{\bullet} \mathrm{ClOH}$ has a maximum corresponding to the structure with a $\mathrm{C}-\mathrm{C}-\mathrm{O}-\mathrm{H}$ dihedral of $91.30^{\circ}$. In this structure, the two non-bonding $\mathrm{e}^{-}$pairs from the O atom are eclipsed with the Cl atom and the $-\mathrm{CH}_{3}$ group, with energy increased by $4.97 \mathrm{kcal} / \mathrm{mol}$ relative to that of the stable conformer, which has the two non-bonding $e^{-}$pairs gauche to the Cl atom and methyl group. The $\mathrm{C}-\mathrm{O}$ torsion potential for $\mathrm{CH}_{3} \mathrm{C} \cdot \mathrm{HOH}$ also has a similar curve; however, the $\mathrm{CH}_{3}--\mathrm{H}$ eclipsed structure for $\mathrm{CH}_{3} \mathrm{C}^{\bullet} \mathrm{ClOH}$ has energy $3.43 \mathrm{kcal} / \mathrm{mol}$ higher than that of
$\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}$ and $\mathrm{C}^{\circ} \mathrm{H}_{2} \mathrm{CH}_{2} \mathrm{OH}$ are also similar and they have lower barriers relative to $\mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{OH}$ and $\mathrm{C}^{\bullet} \mathrm{H}_{2} \mathrm{CCl}_{2} \mathrm{OH}$.

Figure 2.5 Potential barriers for internal rotation about the $\mathrm{C}-\mathrm{O}$ bond of $\mathrm{CH}_{3} \mathrm{C}^{\bullet} \mathrm{HOH}$ and $\mathrm{CH}_{3} \mathrm{C}^{\bullet} \mathrm{ClOH}$.

The calculated rotational barriers about the $\mathrm{C}-\mathrm{O}$ bond of $\mathrm{CH}_{3} \mathrm{C}^{*} \mathrm{HOH}$ and $\mathrm{CH}_{3} \mathrm{C}^{\circ} \mathrm{ClOH}$ are shown in Figure 2.5. The $\mathrm{C}-\mathrm{O}$ torsion potential for $\mathrm{CH}_{3} \mathrm{C}^{\bullet} \mathrm{ClOH}$ has a maximum corresponding to the structure with a C-C-O-H dihedral of $91.30^{\circ}$. In this structure, the two non-bonding $\mathrm{e}^{-}$pairs from the O atom are eclipsed with the Cl atom and the $-\mathrm{CH}_{3}$ group, with energy increased by $4.97 \mathrm{kcal} / \mathrm{mol}$ relative to that of the stable conformer, which has the two non-bonding $\mathrm{e}^{-}$pairs gauche to the Cl atom and methyl group. The $\mathrm{C}-\mathrm{O}$ torsion potential for $\mathrm{CH}_{3} \mathrm{C}^{\bullet} \mathrm{HOH}$ also has a similar curve; however, the $\mathrm{CH}_{3}--\mathrm{H}$ eclipsed structure for $\mathrm{CH}_{3} \mathrm{C}^{\bullet} \mathrm{ClOH}$ has energy $3.43 \mathrm{kcal} / \mathrm{mol}$ higher than that of
the $\mathrm{CH}_{3}--\mathrm{H}$ eclipsed structure for $\mathrm{CH}_{3} \mathrm{C}^{\circ} \mathrm{HOH}$. This is because the non-bonding $\mathrm{e}^{-}$pair from the O atom is eclipsed to the H atom in $\mathrm{CH}_{3} \mathrm{C}^{\bullet} \mathrm{HOH}$; but eclipsed to the Cl atom in $\mathrm{CH}_{3} \mathrm{C}^{\bullet} \mathrm{ClOH}$.

### 2.3.3 Enthalpy of Formation

The total electronic energies are determined at the B3LYP/6-31G(d,p), B3LYP/6$311+\mathrm{G}(3 \mathrm{df}, 2 \mathrm{p}), \operatorname{QCISD}(\mathrm{T}) / 6-31 \mathrm{G}(\mathrm{d}, \mathrm{p})$ and CBSQ//B3LYP/6-31G(d,p) levels. The spin expectation values, $\left\langle S^{2}\right\rangle$, range from 0.760 to 0.781 for the eight target radicals. The values are close to the correct value of 0.75 and suggest no significant error (due to spin contamination) for these radicals.

Table $2.1 \Delta H_{\mathrm{f}}{ }^{\circ} 298$ for Standard Species in Reaction Schemes

| species | $\Delta H_{\mathrm{f} 298}^{\mathrm{o}}(\mathrm{kcal} / \mathrm{mol})$ | species | $\Delta H_{\mathrm{f} 298}^{\mathrm{o}}(\mathrm{kcal} / \mathrm{mol})$ |
| :---: | :---: | :---: | :---: |
| $\mathrm{CH}_{4}$ | $-17.89^{49} \pm 0.07$ | $\mathrm{C}^{*} \mathrm{Cl}_{2} \mathrm{OH}$ | $-20.54{ }^{46} \pm 1.83$ |

| $\mathrm{C}^{*} \mathrm{HClOH}$ | $-14.46{ }^{46} \pm 1.75$ |  |  |

The $\Delta H_{\mathrm{f}}^{\mathrm{o}} 298$ 's for chloro-substituted species are estimated using total energies and isodesmic reactions. Density functional and ab initio calculations with ZPVE and thermal correction are performed for all four compounds in each reaction, and enthalpy of reaction $\Delta H_{\mathrm{rxn}, 298}^{0}$ is calculated. Since $\Delta H_{\mathrm{f}}{ }^{0} 298$ of three compounds, have been
experimentally determined or theoretical calculated, the unknown enthalpy of formation of target compound is obtained. The $\Delta H_{\mathrm{f}}^{\mathrm{o}} 298$ and their respective uncertainties for standard species used in the working reactions are listed in Table 2.1.
2.3.3.1 Mono- and Dichloroethanols. The isodesmic reactions, reaction enthalpies, and $\Delta H_{\mathrm{f}}^{\mathrm{o}} 298$ values for the monochloroethanols and dichloroethanols are tabulated in Appendix Table A.2. The results for $\Delta H_{\mathrm{f}}{ }^{0} 298$ 's in Table A. 2 show very good consistency for $\mathrm{CH}_{3} \mathrm{CHClOH}$ over the seven reactions and all the calculation methods. The $\Delta H_{\mathrm{f}}^{\mathrm{o}} 298$ for $\mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{OH}$ derived from the seven reaction series show consistency over all reactions for the higher level Density Functional calculation; but the $\Delta H_{\mathrm{f}}{ }^{\mathrm{o}} 298$ 's for dichloroethanol derived from reaction series 1,2 and 3 in the CBSQ calculations result in values that are ca. $3 \mathrm{kcal} / \mathrm{mol}$ lower than values of reaction series $4,5,6$ and 7 . The density function results agree with CBSQ results in reactions 4 to 7 . The difference in CBSQ values is suggested due to the changes to the environment of the di-chlorinated carbon in the different reactions schemes. Specifically, the methyl group is retained on the $-\mathrm{CCl}_{2}$ - carbon in reaction series $4,5,6$ and 7 . The methyl group is substituted with a H atom on this $-\mathrm{CCl}_{2}$ - carbon, in reactions 1,2 and 3. The higher-level Density Functional calculations do not show this problem. This data suggests: (i.) substitution of a methyl group with a hydrogen atom does not lead to good cancellation of errors, and (ii.) reactions 4 to 7 are preferred.

The G3MP2 calculations with seven working reactions and MP2(FULL)/6$31 \mathrm{G}(\mathrm{d})$ geometries are used to further validate the enthalpy data. The results from G3MP2 calculation show good agreement in $\Delta H^{0}{ }_{\mathrm{rxn}, 298}$ and $\Delta H_{\mathrm{f}}{ }^{0} 298$ vs reaction set, with
the CBSQ//B3 data. The CBSQ values from the reaction series 4 to 7 are recommended values on both $\mathrm{CH}_{3} \mathrm{CHClOH}$ and $\mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{OH}$. The enthalpy on the pure enantiomer of lowest energy for $\mathrm{CH}_{3} \mathrm{CHClOH}$ is $-68.72 \pm 1.24 \mathrm{kcal} / \mathrm{mol}$ and for $\mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{OH}$ is -75.75 $\pm 1.31 \mathrm{kcal} / \mathrm{mol}$.

### 2.3.3.2 Chloroethoxy and Hydroxy-Chloroethyl Radicals. The $\Delta \mathrm{H}_{\mathrm{f}}{ }^{0} 298$ values of

 chloroethoxy and hydroxy-chloroethyl radicals are calculated based on the $\Delta \mathrm{H}_{\mathrm{f}}{ }^{\circ} 298$ 's for the chloroethanols and several isodesmic reaction series and are listed in Table 2.2. Reaction series $4,5,6$, and 7 for the chloroethoxy radicals are isodesmic, while reactions 1, 2 and 3 are not. The $\Delta \mathrm{H}_{\mathrm{f}}{ }^{0} 298$ for the two chloroethoxy radicals show remarkable consistency at the CBSQ//B3 level for isodesmic reactions, where the standard deviation is within $0.2 \mathrm{kcal} / \mathrm{mol}$. The DFT and $\mathrm{QCISD}(\mathrm{T})$ calculations for the isodesmic reactions show deviation of ca. $\pm 1 \mathrm{kcal} / \mathrm{mol}$ with the CBSQ values.The DFT and QCISD(T) calculations result in still larger variations for nonisodesmic reaction series 1,2 and 3 . CBSQ//B3 calculation results for non-isodesmic reactions are in satisfactory agreement with the isodesmic reactions; but consistently result in $0.5 \mathrm{kcal} / \mathrm{mol}$ higher values for the two chloromethoxy radicals.

The recommended $\Delta H_{\mathrm{f}}{ }_{2}^{\mathrm{o}}$ 號 for the two chloroethoxy radicals are an average of four isodesmic reactions at the $\mathrm{CBSQ} / / \mathrm{B} 3$ calculation level. The $\Delta H_{\mathrm{f}}{ }^{0} 298$ are $-14.79 \pm$ 2.90 and $-21.85 \pm 2.82 \mathrm{kcal} / \mathrm{mol}$ for $\mathrm{CH}_{3} \mathrm{CHClO}^{\circ}$ and $\mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{O}^{\circ}$ respectively.

The $\Delta H_{\mathrm{f}}{ }^{\mathrm{o}} 298$ on the pure enantiomer of lowest energy for the three hydroxy-chloroethyl radicals are an average over the five isodesmic reactions at the $\mathrm{CBSQ} / / \mathrm{B} 3$ level: $-25.92 \pm$ $2.13,-17.62 \pm 2.13$ and $23.85 \pm 2.13 \mathrm{kcal} / \mathrm{mol}$ for $\mathrm{CH}_{3} \mathrm{C}^{\bullet} \mathrm{ClOH}, \mathrm{C}^{\bullet} \mathrm{H}_{2} \mathrm{CHClOH}$, and $\mathrm{C}^{\bullet} \mathrm{H}_{2} \mathrm{CCl}_{2} \mathrm{OH}$, respectively. The CBSQ values show excellent agreement across the five
isodesmic reaction series with a standard deviation on the order of $0.01 \mathrm{kcal} / \mathrm{mol}$. The QCISD(T) also show very good agreement with CBSQ results.

Table 2.2 Reaction Enthalpies at 298 K and Calculated $\Delta H_{\mathrm{f}}^{\mathrm{o}} 298{ }^{\text {a }}$

| Reaction Series | $\begin{gathered} \text { B3LYP } \\ 16-31 \mathrm{G}(\mathrm{~d}, \mathrm{p}) \end{gathered}$ |  | $\begin{gathered} \mathrm{B} 3 \mathrm{LYP} / 6- \\ 311+\mathrm{G}(3 \mathrm{df}, 2 \mathrm{p}) \end{gathered}$ |  | $\begin{aligned} & \hline \operatorname{QCISD}(\mathrm{T}) \\ & 16-31 \mathrm{G}(\mathrm{~d}, \mathrm{p}) \end{aligned}$ |  | $\begin{gathered} \hline \text { CBSQ//B3LYP } \\ / 6-31 \mathrm{G}(\mathrm{~d}, \mathrm{p}) \end{gathered}$ |  |

$-23.85 \pm 0.01$
$\overline{{ }^{a}}$ Reaction enthalpies include thermal correction and zero-point energy. Units in $\mathrm{kcal} / \mathrm{mol}$. ${ }^{\mathrm{b}}$ Average value calculated at the $\mathrm{CBSQ} / / \mathrm{B} 3$ level, and the deviation are between the isodesmic reactions.

The error limits of $\Delta H_{\mathrm{f}}{ }_{298}$ for above species are calculated by adding the deviations between the isodesmic reactions and the maximum uncertainties in the $\Delta H_{\mathrm{f}}^{\mathrm{o}} 298$ of reference species.
2.3.3.3 Comparison with Literature Enthalpies. The $\Delta H_{\mathrm{f}}{ }^{\mathrm{o}} 298$ for monochloroethanol and the corresponding radicals are found in literature for comparisons. Sekušak et al. ${ }^{61}$ estimated $\Delta H_{\mathrm{f}}{ }^{\mathrm{o}} 298$ of $\mathrm{CH}_{3} \mathrm{CHClOH}$ to be $-69.7 \mathrm{kcal} / \mathrm{mol}$ by Benson's group additivity method, and this is in agreement with our recommend value, $-68.63 \pm 1.24 \mathrm{kcal} / \mathrm{mol}$. Sekušak et al. also calculated the $\Delta H_{\mathrm{f}}{ }^{\circ} 298$ of $\mathrm{C}^{\circ} \mathrm{H}_{2} \mathrm{CHClOH}$ at the MP2/aug-cc-pVTZ level to be $-23.0 \mathrm{kcal} / \mathrm{mol}$ by reaction $\mathrm{CH}_{2} \mathrm{CHCl}+\mathrm{OH}^{\bullet} \rightarrow \mathrm{C}^{*} \mathrm{H}_{2} \mathrm{CHClOH}$, which is a nonisodesmic reaction. Wallington et al. ${ }^{62}$ estimated the $\Delta H_{\mathrm{f}}^{\mathrm{o}} 298$ of $\mathrm{CH}_{3} \mathrm{CHClO}^{\circ}$ to be -18.9 $\mathrm{kcal} / \mathrm{mol}$ by assuming that the difference in the $\Delta H_{\mathrm{f} 298}^{\mathrm{o}}$ between chloromethoxy and methoxy radicals is the same as that between $\alpha$-chloroethoxy and ethoxy radicals. Hou et al. ${ }^{63}$ calculated the $\Delta H_{\mathrm{f}}^{\mathrm{o}}{ }_{298}$ for $\mathrm{CH}_{3} \mathrm{CHClO}^{\circ}, \mathrm{CH}_{3} \mathrm{C}^{\circ} \mathrm{ClOH}$ and $\mathrm{C}^{\circ} \mathrm{H}_{2} \mathrm{CHClOH}$ at the G2(MP2, SVP) level to be $-17.8,-29.7$, and $-21.3 \mathrm{kcal} / \mathrm{mol}$, respectively; however, they did not provide calculation details or indicate the method of analysis. The recommended $\Delta H_{\mathrm{f}}{ }^{\mathrm{o}} 298$ values for $\mathrm{CH}_{3} \mathrm{CHClO}^{*}, \mathrm{CH}_{3} \mathrm{C}^{\circ} \mathrm{ClOH}$ and $\mathrm{C}^{\circ} \mathrm{H}_{2} \mathrm{CHClOH}$ are consistently 3 to 4 $\mathrm{kcal} / \mathrm{mol}$ higher than data estimated by Hou et al. ${ }^{9}$ The consistent difference between our values and those of Hou et. al. could result from the differences in $\Delta H_{\mathrm{f}}{ }^{\mathrm{o}} 298$ of the parent $\mathrm{CH}_{3} \mathrm{CHClOH}$, which is used in each working reaction.

The G3MP2 calculations for the two saturated chloroethanols show excellent agreement with the other calculations. The precision of our calculated enthalpies on $\mathrm{CH}_{3} \mathrm{CHClOH}$ over a range of calculation methods and working reactions does not provide any support for a different value. The good agreement observed over the several
calculation levels for $\alpha$-chloroethanol and the corresponding radicals provides support that our calculations are consistent across different calculation methods. The QCISD(T) results also indicate that our values are consistent with HF and MP2 calculations. The high level $\operatorname{QCISD}(\mathrm{T}) / 6-31 \mathrm{G}(\mathrm{d}, \mathrm{p}), \mathrm{CBSQ} / / \mathrm{B} 3$, and G3MP2 calculations all predict very similar enthalpies. The recommended data are based on analysis of conformer energies from internal rotations and use of the lowest energy conformers.
2.3.3.4 Enthalpy of Rotational Conformers. Two conformers are present in chloroethanols and hydroxyl chloroethyl radicals (shown in Figures 2.3, 2.4 and 2.5); one is R-$\mathrm{H}\left(\mathrm{R}=\mathrm{CH}_{3}\right.$ or $\left.\mathrm{CH}_{2}\right)$ anti conformer and the other is $\mathrm{R}-\mathrm{H}$ gauche conformer. The total electronic energies of these conformers are calculated at the B3LYP/6-31G(d,p), B3LYP/6-311+G(3df,2p), $\quad$ QCISD(T)/6-31G(d,p) and $\quad$ CBSQ//B3LYP/6-31G(d,p) calculation levels. The energy differences between the conformers are listed in Table 2.3.

Table $2.3 \Delta H_{f}^{\mathrm{o}} 298$ of Conformers and Relative Fraction

${ }^{\mathrm{a}}$ The rotational conformer with the lowest energy. ${ }^{\text {b }}$ The rotational conformer with higher energy. ${ }^{\text {c }}$ Enthalpy of formation at 298 K calculated at the CBSQ//B3 level.

The $\Delta H_{\mathrm{f}}^{\mathrm{o}} 298$ of the rotational conformers are determined from values calculated at the $\mathrm{CBSQ} / / \mathrm{B} 3$ level using isodesmic reaction schemes. The statistical distribution and
overall $\Delta H_{\mathrm{f}}{ }^{\mathrm{o}} 298$ of the chloroethanols and hydroxy-chloroethyl radicals are also listed in Table 2.3. It can be seen that energy difference between the conformers decreases for the higher level calculations. The energy differences at the CBSQ//B3 calculation level are used to calculate the statistical distribution of rotational conformers.
2.3.3.5 Bond Energies. The $\mathrm{RO}-\mathrm{H}, \mathrm{R}-\mathrm{OH}, \mathrm{R}-\mathrm{H}$, and $\mathrm{R}-\mathrm{Cl}$ bonds dissociation energies are presented in Table 2.4. They are estimated using the $\Delta H_{\mathrm{f}}^{\mathrm{o}} 298$ of chloroethanols and the radicals from this work, plus reference radicals.

Table 2.4 Bond Energies

| reaction series | bond energy (kcal/mol) |
| :---: | :---: |
| RO-H |  |
| $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH} \rightarrow \mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{O}^{\bullet}+\mathrm{H}^{+}$ | 104.32 |
| $\mathrm{CH}_{3} \mathrm{CHClOH} \rightarrow \mathrm{CH}_{3} \mathrm{CHClO}^{+}+\mathrm{H}^{\bullet}$ | 105.94 |
| $\mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{OH} \rightarrow \mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{O}^{*}+\mathrm{H}^{*}$ | 105.97 |
| $\mathrm{R}-\alpha-\mathrm{H}$ |  |
| $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH} \rightarrow \mathrm{CH}_{3} \mathrm{C}^{*} \mathrm{HOH}+\mathrm{H}^{\bullet}$ | 94.88 |
| $\mathrm{CH}_{3} \mathrm{CHClOH} \rightarrow \mathrm{CH}_{3} \mathrm{C}^{*} \mathrm{ClOH}+\mathrm{H}^{*}$ | 94.84 |
| $\mathrm{R}-\beta-\mathrm{H}$ |  |
| $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH} \rightarrow \mathrm{C}^{*} \mathrm{H}_{2} \mathrm{CH}_{2} \mathrm{OH}+\mathrm{H}^{\bullet}$ | 102.52 |
| $\mathrm{CH}_{3} \mathrm{CHClOH} \rightarrow \mathrm{C}^{*} \mathrm{H}_{2} \mathrm{CHClOH}+\mathrm{H}^{*}$ | 103.22 |
| $\begin{gathered} \mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{OH} \rightarrow \mathrm{C}^{*} \mathrm{H}_{2} \mathrm{CCl}_{2} \mathrm{OH}+\mathrm{H}^{+} \\ \mathrm{R}-\mathrm{Cl} \end{gathered}$ | 104.03 |
| $\mathrm{CH}_{3} \mathrm{CHClOH} \rightarrow \mathrm{CH}_{3} \mathrm{C}^{*} \mathrm{HOH}+\mathrm{Cl}^{\bullet}$ | 84.21 |
| $\mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{OH} \rightarrow \mathrm{CH}_{3} \mathrm{C}^{*} \mathrm{ClOH}+\mathrm{Cl}^{\bullet}$ | 78.75 |
| R-ROH |  |
| $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH} \rightarrow \mathrm{CH}_{3}{ }^{+}+\mathrm{C}^{\bullet} \mathrm{H}_{2} \mathrm{OH}$ | 86.97 |
| $\mathrm{CH}_{3} \mathrm{CHClOH} \rightarrow \mathrm{CH}_{3}{ }^{+}+\mathrm{C}^{*} \mathrm{HClOH}$ | 88.99 |
| $\underset{R--\mathrm{OH}}{\mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{OH} \rightarrow \mathrm{CH}_{3}{ }^{\circ}+\mathrm{C}^{\circ} \mathrm{Cl}_{2} \mathrm{OH}}$ | 90.00 |
| $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH} \rightarrow \mathrm{CH}_{3} \mathrm{CH}_{2}{ }^{+}+\mathrm{OH}^{\bullet}$ | 94.35 |
| $\mathrm{CH}_{3} \mathrm{CHClOH} \rightarrow \mathrm{CH}_{3} \mathrm{CHCl}^{+}+\mathrm{OH}^{+}$ | 97.21 |
| $\mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{OH} \rightarrow \mathrm{CH}_{3} \mathrm{CCl}_{2}{ }^{\text {+ }} \mathrm{OH}^{+}$ | 97.58 |

The $\mathrm{R}-\mathrm{OH}$ bond energies increase from $94.35 \mathrm{kcal} / \mathrm{mol}$ in $\mathrm{CH}_{3} \mathrm{CH}_{2}-\mathrm{OH}$ to 97 $\mathrm{kcal} / \mathrm{mol}$ in $\mathrm{CH}_{3} \mathrm{CHCl}-\mathrm{OH}$ and $\mathrm{CH}_{3} \mathrm{CCl}_{2}-\mathrm{OH}$. The second chlorine does not appear to affect an increase on the $\mathrm{R}-\mathrm{OH}$ bond energies. This can be explained by a negative
hyperconjugation effect. The hydroxyl group includes two nonbonding $\mathrm{e}^{-}$pairs centered on oxygen, one pair can interact strongly with $\sigma^{*}\left(\mathrm{C}-\mathrm{Cl}_{1}\right)$ orbital, however, the other pair cannot effectively overlap with $\sigma^{*}\left(\mathrm{C}_{-1} \mathrm{Cl}_{2}\right)$ orbital. The RO-H bond energy for mono, and dichloroethanol increases $1.6 \mathrm{kcal} / \mathrm{mol}$ relative to that of ethanol; this is because the $\mathrm{O}-\mathrm{H}$ bond is heterolytic rather than homolytic, and it is slightly stabilized by negative hyperconjugation even though the $\mathrm{O}-\mathrm{H}$ bond is not directly perturbed by the chlorine(s). ${ }^{44}$

The $\mathrm{C}-\mathrm{Cl}$ bond energies decrease from 84.21 to $78.75 \mathrm{kcal} / \mathrm{mol}$ with successive addition of chlorine. However, the $\mathrm{C}-\mathrm{COH}$ bond energy increases from 86.97 in $\mathrm{CH}_{3}-\mathrm{CH}_{2} \mathrm{OH}$ to 88.99 in $\mathrm{CH}_{3}-\mathrm{CHClOH}$ and to $90.00 \mathrm{kcal} / \mathrm{mol}$ in $\mathrm{CH}_{3}-\mathrm{CCl}_{2} \mathrm{OH}$. The $\mathrm{C}-\alpha-\mathrm{H}$ bond energies in ethanol and chloroethanol are quite similar; they show a very slight decrease from 94.88 to 94.84 with the mono-chlorine substitution. Normally it is expected a decrease in bond energy on the $\mathrm{C}-\alpha-\mathrm{H}$ bond in chloroethanol relative to ethanol using the trends of $\mathrm{C}-\mathrm{H}$ bond energies in the series: $\mathrm{CH}_{4}, \mathrm{CH}_{3} \mathrm{Cl}, \mathrm{CH}_{2} \mathrm{Cl}_{2}$, and $\mathrm{CHCl}_{3}$, and $\mathrm{CH}_{3} \mathrm{OH}, \mathrm{CH}_{2} \mathrm{ClOH}$, and $\mathrm{CHCl}_{2} \mathrm{OH}$ studied previously. ${ }^{46}$ But no indication of this trend is found in the $\mathrm{C}-\alpha-\mathrm{H}$ bond strength of $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}$ and $\mathrm{CH}_{3} \mathrm{CHClOH}$. In contrast, the $\mathrm{C}-\beta$ - H bond energies in $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}, \mathrm{CH}_{3} \mathrm{CHClOH}$ and $\mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{OH}$ show a consistent increase: $102.52,103.22$ and $104.03 \mathrm{kcal} / \mathrm{mol}$, respectively.

### 2.3.4 Entropy and Heat Capacity

$S^{0}{ }_{298}$ and $C_{p}(T)$ 's calculation results using the B3LYP/6-31G(d,p) determined geometries and harmonic frequencies are summarized in Table 2.5. Harmonic vibrational frequencies and moments of inertia are listed in Table 2.6.

Table 2.5 Ideal Gas-phase Thermodynamic Properties ${ }^{\text {a }}$

|  |  |  |  |  |  |  |  |  |  |  |  | 854.6 |

The two lowest frequencies (one in $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{O}^{\bullet}, \mathrm{CH}_{3} \mathrm{CHClO}^{\bullet}$ and $\mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{O}^{\bullet}$ ) are omitted in calculation of $S^{\circ}{ }_{298}$ and $C_{p}\left(T^{\prime}\right)^{\prime}$ 's; but their contributions are placed by values from analysis of the internal rotations. TVR, represent the sum of the contributions from translation, vibration and external rotation for $S_{298}^{0}$ and $C_{p}(T)$ 's. I.R., represent the contributions from hindered internal rotations about $\mathrm{C}-\mathrm{C}$ and $\mathrm{C}-\mathrm{O}$ bonds for $S^{0}{ }_{298}$ and $C_{p}(T)$ 's. The calculations are based on optimized geometries and rotational potential
curves from the B3LYP/6-31G(d,p) data. There are differences in barrier height calculated at the B3LYP/6-31G(d,p) and the MP2(FULL)/6-31G(d) levels of theory, as discussed in the rotation barrier section. The resulting differences in $S^{0}{ }_{298}$ and $C_{p}(T)$ 's are however small. In the most extreme case, the barrier height varies by $2 \mathrm{kcal} / \mathrm{mol}$ for $\mathrm{C}^{\bullet} \mathrm{H}_{2} \mathrm{CCl}_{2} \mathrm{OH}$ in the two calculations.

The resulting difference in the contribution to $S^{0}{ }_{298}$ is ca. $0.7 \mathrm{cal} / \mathrm{mol}-\mathrm{K}$, and the maximum difference for the contribution to $C_{p}(T)$ 's is ca. $0.5 \mathrm{cal} / \mathrm{mol}-\mathrm{K}$. This indicates that the maximum error for the contribution to $S^{0}{ }_{298}$ and $C_{p}(T)$ 's from one internal rotor is less than $0.7 \mathrm{cal} / \mathrm{mol}-\mathrm{K}$.

### 2.3.5 Group Additivity Values

Group additivity ${ }^{64}$ is a straightforward and reasonably accurate calculation method to estimate thermodynamic properties of hydrocarbons and oxygenated hydrocarbons; it is particularly useful for application to larger molecules and codes or databases for thermochemical properties and reaction mechanism generation. The $\mathrm{C} / \mathrm{C} / \mathrm{Cl} / \mathrm{H} / \mathrm{O}$ and $\mathrm{C} / \mathrm{C}^{2} \mathrm{Cl}_{2} / \mathrm{O}$ group values are derived from the thermodynamic property data of $\mathrm{CH}_{3} \mathrm{CHClOH}$ and $\mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{OH}$ respectively. The group values for $\Delta H_{\mathrm{f}}{ }^{\mathrm{o}} 298$ and $C_{p}{ }^{\prime}$ s of $\mathrm{C} / \mathrm{C} / \mathrm{Cl} / \mathrm{H} / \mathrm{O}$ are calculated on the basis of:

$$
\left(\mathrm{CH}_{3} \mathrm{CHClOH}\right)=(\mathrm{C} / \mathrm{C} / \mathrm{Cl} / \mathrm{H} / \mathrm{O})+\left(\mathrm{C} / \mathrm{C} / \mathrm{H}_{3}\right)+(\mathrm{O} / \mathrm{C} / \mathrm{H})
$$

and $\mathrm{S}^{0}{ }_{298}$ of $\mathrm{C} / \mathrm{C} / \mathrm{Cl} / \mathrm{H} / \mathrm{O}$ is calculated on the basis of:

$$
\left(\mathrm{CH}_{3} \mathrm{CHClOH}\right)=(\mathrm{C} / \mathrm{C} / \mathrm{Cl} / \mathrm{H} / \mathrm{O})+\left(\mathrm{C} / \mathrm{C} / \mathrm{H}_{3}\right)+(\mathrm{O} / \mathrm{C} / \mathrm{H})+\mathrm{R} \ln (\mathrm{OI})-\mathrm{R} \ln (\sigma)
$$

where $\mathrm{R}=1.987 \mathrm{cal} / \mathrm{mol} \mathrm{K}$, OI stands for optical isomer number and $\sigma$ symmetry number. The group values of $\mathrm{C} / \mathrm{C} / \mathrm{Cl}_{2} / \mathrm{O}$ are estimated in the same manner. The
thermochemical properties on $\mathrm{C} / \mathrm{C} / \mathrm{H}_{3}$ and $\mathrm{O} / \mathrm{C} / \mathrm{H}$ group are taken from the existing literature value. ${ }^{65}$ The two derived carbon-chlorine-oxygen group values are listed in Table 2.6, which shows that the group values for $\Delta H_{\mathrm{f}}{ }^{0} 298$ decrease with increased number of chlorine atom.

Table 2.7 Group Values

| Groups | $\Delta H_{\mathrm{f} 298{ }^{\mathrm{o}}}{ }^{\mathrm{o}}$ | $S_{298}{ }^{\mathrm{b}}$ | $C_{p} 300^{\mathrm{b}}$ | $C_{p} 400$ | $C_{p} 500$ | $C_{p} 600$ | $C_{p} 800$ | $C_{p} 1000$ | $C_{p} 1500$ |

${ }^{\mathrm{a}}$ Units in $\mathrm{kcal} / \mathrm{mol}$. ${ }^{\mathrm{b}}$ Units in $\mathrm{cal} / \mathrm{mol}-\mathrm{K}$.

### 2.3.6 Hydrogen Bond Increment Group Values

A method to estimate thermochemical properties for radicals from the corresponding properties of the parent with a H atom bonded to the radical site using a single group to modify the parent properties (hydrogen bond increment (HBI) group) has been reported by Lay et al. ${ }^{66}$ A HBI group for $\Delta H_{\mathrm{f}}{ }^{0} 298$ reflects the enthalpy change due to loss of a H atom ${ }^{66}$ from a stable parent molecule in the form of the $\mathrm{R}-\mathrm{H}$ bond energy. Hydrogen Bond Increment group values for the chloro-oxy-ethyl radicals are derived using the thermodynamic property data of chloroethoxy and hydroxy-chloroethyl radicals and parent chloroethanols.

As an example, the bond energy of $\mathrm{CH}_{3} \mathrm{CHClO}-\mathrm{H}$ is based on the $\Delta H^{\circ}{ }_{\mathrm{rxn}, 2} 298$ of the homolytic reaction: $\left(\mathrm{CH}_{3} \mathrm{CHClOH}\right)=\left(\mathrm{CH}_{3} \mathrm{CHClO}^{\circ}\right)+\mathrm{H}$
$\Delta S^{\circ}{ }_{298}$ and $\Delta C_{p}$ are determined more directly, as the differences in respective properties of the molecule versus the radical in such a way that the HBI values for $S^{\circ}{ }_{298}$ and $C_{p}(T)$ are added to the parent values to form the radical.

$$
\begin{aligned}
& \text { HBI } C_{p}\left(T_{i}\right)\left(\mathrm{CH}_{3} \mathrm{CHClO}^{\circ}\right)=C_{p}\left(T_{i}\right) \mathrm{CH}_{3} \mathrm{CHClO}^{\bullet}-C_{p}\left(T_{i}\right)\left(\mathrm{CH}_{3} \mathrm{CHClOH}\right) \\
& \mathrm{HBI} S^{0}{ }_{298}\left(\mathrm{CH}_{3} \mathrm{CHClO}^{*}\right)=S^{\circ}{ }_{298}\left(\mathrm{CH}_{3} \mathrm{CHClO}^{*}\right)-S^{\circ}{ }_{298}\left(\mathrm{CH}_{3} \mathrm{CHClOH}\right)+\mathrm{R} \ln \left(\sigma_{\mathrm{CH} 3 \mathrm{CHCIO}} / \sigma_{\mathrm{CH} 3 \mathrm{CHClOH}}\right)
\end{aligned}
$$

Effects for changes in symmetry between the radical and parent are not included in the HBI group; but are included in evaluation of the entropy of each species separately. The following species have optical isomer number of two due to the different constituents on the carbon bonded with chlorine: $\mathrm{CH}_{3} \mathrm{CHClOH}, \mathrm{CH}_{3} \mathrm{CHClO}^{\circ}$, and $\mathrm{C}^{\circ} \mathrm{H}_{2} \mathrm{CHClOH}$. The HBI values for other radical species are estimated in the same manner as $\mathrm{CH}_{3} \mathrm{CHClO}^{\bullet}$ above and they are listed in Table 2.7.

Table 2.8 Hydrogen Bond Increment (HBI) Group Values

| Groups | bond energy ${ }^{2}$ | $S_{298}^{b^{b}}$ | $C_{p} 300^{6}$ | $C_{p} 400$ | $C_{p} 500$ | $C_{p} 600$ | $C_{p} 800$ | $C_{p} 1000$ | $C_{p} 1500$ |

| $\mathrm{C}^{\bullet} \mathrm{H}_{2} \mathrm{CCl}_{2} \mathrm{OH}$ | 104.03 | 2.73 | 0.88 | 0.16 | -0.78 | -1.64 | -2.89 | -3.68 | -4.69 |

${ }^{\mathrm{a}}$ Units in $\mathrm{kcal} / \mathrm{mol}$. ${ }^{\mathrm{b}}$ Units in $\mathrm{cal} / \mathrm{mol}-\mathrm{K}$.

The HBI group values for bond energy of $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{O}^{\bullet}$ and $\mathrm{CH}_{3} \mathrm{CHClO}^{\bullet}$ are similar to the values of $\mathrm{CH}_{3} \mathrm{O}^{\bullet}$ and $\mathrm{CH}_{2} \mathrm{ClO}^{\bullet}$ derived from previous work, ${ }^{46}$ ca. $105 \mathrm{kcal} / \mathrm{mol}$. The HBI group values for the bond energy of $\mathrm{CH}_{3} \mathrm{C}^{\bullet} \mathrm{HOH}$ and $\mathrm{CH}_{3} \mathrm{C}^{\bullet} \mathrm{ClOH}$ are similar to those of $\mathrm{C}^{\bullet} \mathrm{H}_{2} \mathrm{OH}$ and $\mathrm{C}^{\bullet} \mathrm{HClOH},{ }^{46}$ ca. $95 \mathrm{kcal} / \mathrm{mol}$. The HBI group values of entropy for $\mathrm{CH}_{3} \mathrm{O}^{\bullet}$ and $\mathrm{CCl}_{3} \mathrm{O}^{\bullet}$ are -4.18 and $-0.58 \mathrm{cal} / \mathrm{mol}-\mathrm{K}$ from the previous work, ${ }^{46}$ these two values did not include electronic orbital degeneracy of 2 by $C_{3 v}$ symmetry because the optimized geometries at the B3LYP/6-31G(d,p) level resulted in $\mathrm{C}_{s}$ symmetry for the two molecules. The $\mathrm{C}_{s}$ symmetry is due to the Jahn-Taller distortion and a vibronic coupling
where the asymmetric vibrational e modes couple to the degenerate E electronic states. ${ }^{67}$ Barckholtz et al. ${ }^{67}$ report that an effective electronic degeneracy of $\mathrm{CH}_{3} \mathrm{O}^{*}$ is 2 because of the dynamic nature of the Jahn-Taller effect and the relatively larger zero-point vibration energy in $\mathrm{CH}_{3} \mathrm{O}^{\circ}$ (degeneracy is in addition to the spin states). When the electronic orbital degeneracy for $\mathrm{CH}_{3} \mathrm{O}^{*}$ and $\mathrm{CCl}_{3} \mathrm{O}^{\bullet}$ is 2 , the $S^{0}{ }_{298}$ for $\mathrm{CCl}_{3} \mathrm{O}^{*}$ is $80.41 \mathrm{cal} / \mathrm{mol}-\mathrm{K}$ rather than $79.03 \mathrm{cal} / \mathrm{mol}-\mathrm{K}$, and the HBI group values for entropy of $\mathrm{CH}_{3} \mathrm{O}^{\circ}$ and $\mathrm{CCl}_{3} \mathrm{O}^{\circ}$ are 2.80 and $0.80 \mathrm{cal} / \mathrm{mol}-\mathrm{K}$. For $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{O}^{\circ}$, the substitution of a hydrogen in $\mathrm{CH}_{3} \mathrm{O}^{\circ}$ with a methyl group perturbs the $\mathrm{C}_{3 v}$ geometry and thus slightly lifts the electronic degeneracy present in $\mathrm{CH}_{3} \mathrm{O}^{\circ}$. At room temperature, the HBI group value of entropy for $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{O}^{\circ}$ is $-0.45 \mathrm{cal} / \mathrm{mol}-\mathrm{K}$ without the electronic orbital degeneracy. However, Ramond et al. ${ }^{68}$ report that the splitting between the ground $\tilde{\mathrm{A}}^{2} \mathrm{~A}^{\prime \prime}$ and the first $\tilde{X}^{2} \mathrm{~A}^{\prime}$ excited states of $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{O}$ - is very small, $355 \pm 10 \mathrm{~cm}^{-1}$. The effective electronic degeneracy of $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{O}^{\bullet}$ at room temperature can then be considered as 2 , and this gives the HBI group values of entropy for $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{O}^{*}$ is $0.93 \mathrm{cal} / \mathrm{mol}-\mathrm{K}$. The electronic degeneracy present in $\mathrm{CH}_{3} \mathrm{O}^{\bullet}$ for $\mathrm{CH}_{3} \mathrm{CHClO}^{\bullet}$ and $\mathrm{CH}_{3} \mathrm{CCl}_{2} \mathrm{O}^{\bullet}$ radicals will be removed by the orbital splitting.

## $2.4 \alpha$-Chlorinated Propanol and Radicals

### 2.4.1 Geometries

The optimized geometric parameters along with vibrational frequencies and moments of inertia for six target species are presented in the Appendix (Table A.3). The lowest energy conformations of $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CClOH},\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CClO}^{\circ}$ and $\mathrm{C}^{\circ} \mathrm{H}_{2} \mathrm{CCl}(\mathrm{OH}) \mathrm{CH}_{3}$ exhibit the
anomeric effect, i.e., a delocalization of the lone pair electron on the oxygen with the antibonding $\sigma^{*}$ orbital of the $\mathrm{C}-\mathrm{Cl}$ bond. Due to the anomeric effect, the $\mathrm{C}-\mathrm{O}$ bond length decreases significantly with chlorine substitution $\left(1.4296 \AA\right.$ in $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CHOH}$, $1.3843 \AA$ in $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CClOH} ; 1.3749 \AA$ in $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CHO}^{\bullet}, 1.3178 \AA$ in $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CClO}^{\bullet} ; 1.4354$ $\AA$ in $\mathrm{C}^{\bullet} \mathrm{H}_{2} \mathrm{CH}(\mathrm{OH}) \mathrm{CH}_{3}$ and $1.3674 \AA$ in $\left.\mathrm{C}^{\bullet} \mathrm{H}_{2} \mathrm{CCl}(\mathrm{OH}) \mathrm{CH}_{3}\right)$. The anomeric effect can also be seen in the $\mathrm{C}-\mathrm{Cl}$ bond length, which is longer than a normal $\mathrm{C}-\mathrm{Cl}$ bond $\left(1.8995 \AA\right.$ in $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CClOH}, 1.9094 \AA$ in $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CClO}^{\bullet}, 2.0598 \AA$ in $\left.\mathrm{C}^{\bullet} \mathrm{H}_{2} \mathrm{CCl}(\mathrm{OH}) \mathrm{CH}_{3}\right)$ as predicted by the DFT calculations. The $\mathrm{C}-\mathrm{Cl}$ bond in $\mathrm{C}^{\bullet} \mathrm{H}_{2} \mathrm{CCl}(\mathrm{OH}) \mathrm{CH}_{3}$ is $0.1 \AA$ longer than in the other two chloro species due to hyperconjugation between $-\mathrm{CH}_{2}{ }^{\bullet}$ center and the $\sigma^{*}(\mathrm{C}-\mathrm{Cl})$ molecular orbital in its lowest energy conformer. Because $\mathrm{p}-\pi$ orbital overlap implies transfer of electron density, the $\mathrm{C}-\mathrm{Cl}$ bond becomes weaker and longer, while the $\mathrm{C}-\mathrm{C}$ bond gets stronger and shorter. The $\mathrm{C}-\mathrm{C}$ bond length in $\mathrm{C}^{\bullet} \mathrm{H}_{2} \mathrm{CCl}(\mathrm{OH}) \mathrm{CH}_{3}$ is $1.44 \AA$ which shorter than the normal, $1.53 \AA$. The MP2(full)/6$31 \mathrm{~g}(\mathrm{~d}, \mathrm{p})$ geometry optimization predicts tight structures for these species, and gives the $\mathrm{C}-\mathrm{Cl}$ bond length $1.8299 \AA, 1.8294 \AA$, and $1.8640 \AA$, respectively; these data also suggest that an anomeric effect and hyperconjugation exist in these species.

The DFT calculations predict a non-planar structure for $-\mathrm{C}^{\circ} \mathrm{H}_{2}$ group in 2-hydroxy-propyl and 2-chloro-2-hydroxy-propyl radicals, where the inversion frequencies for the methylene group are 566.0 and $672.8 \mathrm{~cm}^{-1}$, respectively. The density functional optimized geometry for $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CHOH}$ gives the $\angle \mathrm{H}_{\mathrm{c}}-\mathrm{C}-\mathrm{O}-\mathrm{H}_{0}$ dihedral angle $180.0^{\circ}$, indicating that there is a mirror plane between the two methyl groups, i.e., $C_{s}$ symmetry in $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CHOH}$. The density functional structure also predicts $C_{s}$ symmetry in
$\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CHO}{ }^{\circ}$. The symmetry number is assigned as 18 for $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CHOH}$ and $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CHO}{ }^{\circ}$ on the basis of these data.

### 2.4.2 Rotational Barriers

Potential energy as a function of torsion angle was determined by scanning the dihedral angles from $0^{\circ}$ to $360^{\circ}$ at $15^{\circ}$ increments and allowing the remaining molecular structural parameters to be optimized at the B3LYP/6-31G(d,p) level. The $\mathrm{C}^{*} \mathrm{H}_{2} \mathrm{CCl}(\mathrm{OH}) \mathrm{CH}_{3}$ is an exception, here the $\mathrm{C}-\mathrm{Cl}$ bond length was constrained when scanning the $\mathrm{H}_{\mathrm{c}}-\mathrm{C}-\mathrm{C}-\mathrm{O}$ and C-C-O-H dihedral angles in $\mathrm{C}^{\circ} \mathrm{H}_{2} \mathrm{CCl}(\mathrm{OH}) \mathrm{CH}_{3}$. This is a result of the weak $\mathrm{C}-\mathrm{Cl}$ bond in this radical; it requires only $18 \mathrm{kcal} / \mathrm{mol}$ for $\beta$-scission to form 2-hydroxy propene +Cl atom. The barrier of a given rotation was then calculated as the difference between the highest points on the potential energy surface and the corresponding most stable conformer. The geometries at the points of minima and maxima were fully optimized when possible.

The calculated rotational barriers about the $\mathrm{CH}_{3}-\mathrm{C}_{\mathrm{sp} 3}$ bond of the six target species are shown in Figure 2.6. All the curves for $\mathrm{C}_{\mathrm{sp} 3} \mathrm{C}_{\mathrm{sp} 3}$ torsion potential are symmetric and show a 3 -fold symmetry with barriers between 2.72 and $4.26 \mathrm{kcal} / \mathrm{mol}$. The barriers for the $\mathrm{CH}_{3}-\mathrm{C}_{\mathrm{sp} 3}$ torsion of chloro-substituted species are higher than those of nonchlorinated species and the barriers for stable parent are higher than those of the corresponding radicals probably due to reduced steric effect by the radical carbon groups. Two $\mathrm{C}_{\mathrm{sp} 3}-\mathrm{C}_{\mathrm{sp} 3}$ rotational curves for $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CClOH}$ are shown in Figure 2.6, and one is $0.55 \mathrm{kcal} / \mathrm{mol}$ higher than the other because the hydroxyl H atom orients toward one methyl group resulting in a steric interaction.

Figure 2.6 Potential barriers for internal rotation about the $\mathrm{C}-\mathrm{C}$ bond of $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CHOH}$, $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CClOH},\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CHO}^{\bullet},\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CClO}^{\bullet}, \mathrm{C}^{\bullet} \mathrm{H}_{2} \mathrm{CH}(\mathrm{OH}) \mathrm{CH}_{3}$ and $\mathrm{C}^{\bullet} \mathrm{H}_{2} \mathrm{CCl}(\mathrm{OH}) \mathrm{CH}_{3}$.

Figure 2.7 shows the two-fold rotational barriers about the $\mathrm{CH}_{2}-\mathrm{C}_{\text {sp } 3}$ bond for the $\mathrm{C}^{\bullet} \mathrm{H}_{2} \mathrm{CCl}(\mathrm{OH}) \mathrm{CH}_{3}$ and the $\mathrm{C}^{\bullet} \mathrm{H}_{2} \mathrm{CH}(\mathrm{OH}) \mathrm{CH}_{3}$ radicals. The $\mathrm{H}--\mathrm{OH}$ eclipsed conformer of $\mathrm{C}^{\bullet} \mathrm{H}_{2} \mathrm{CCl}(\mathrm{OH}) \mathrm{CH}_{3}$ has the lowest energy due to the interaction between the H atom in $\mathrm{CH}_{2}$ group and the O atom (interatomic distance is $2.528 \AA$ ). The barrier height for $\mathrm{C}^{\bullet} \mathrm{H}_{2} \mathrm{CCl}(\mathrm{OH}) \mathrm{CH}_{3}$ is $3.6 \mathrm{kcal} / \mathrm{mol}$ higher than that of $\mathrm{C}^{\bullet} \mathrm{H}_{2} \mathrm{CH}(\mathrm{OH}) \mathrm{CH}_{3}$, probably still due to the electrostatic interaction between the Cl atom and the H atom on the $-\mathrm{C}^{\bullet} \mathrm{H}_{2}$ group (the interatomic distance $2.83 \AA$ ) on the barrier top.

Figure 2.7 Potential barriers for internal rotation about the $\mathrm{C}-\mathrm{C}$ bond of $\mathrm{C}^{\bullet} \mathrm{H}_{2} \mathrm{CH}(\mathrm{OH}) \mathrm{CH}_{3}$ and $\mathrm{C}^{\bullet} \mathrm{H}_{2} \mathrm{CCl}(\mathrm{OH}) \mathrm{CH}_{3}$.

Figure 2.8 Potential barriers for internal rotation about the $\mathrm{C}-\mathrm{O}$ bond of $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CClOH}$, $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CClOH}, \mathrm{C}^{\bullet} \mathrm{H}_{2} \mathrm{CH}(\mathrm{OH}) \mathrm{CH}_{3}$ and $\mathrm{C}^{\bullet} \mathrm{H}_{2} \mathrm{CCl}(\mathrm{OH}) \mathrm{CH}_{3}$.

The calculated rotational barriers about the $\mathrm{C}-\mathrm{O}$ bond of $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CClOH}$, $\mathrm{C}^{\bullet} \mathrm{H}_{2} \mathrm{CCl}(\mathrm{OH}) \mathrm{CH}_{3},\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CHOH}$, and $\mathrm{C}^{\bullet} \mathrm{H}_{2} \mathrm{CH}(\mathrm{OH}) \mathrm{CH}_{3}$ are shown in Figure 2.8. There are three conformers in $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CHOH}$; two are the $\mathrm{H}_{0}-\mathrm{H}_{\alpha}$ gauche conformers (subscript " o " stands for oxygen atom), and one is the $\mathrm{H}_{0}-\mathrm{H}_{\alpha}$ anti conformer. The energy for the $\mathrm{H}_{0}-$ $\mathrm{H}_{\alpha}$ anti conformer is only $0.08 \mathrm{kcal} / \mathrm{mol}$ lower than that of the $\mathrm{H}_{0}-\mathrm{H}_{\alpha}$ gauche conformer, so the three conformers should be equally populated at room temperature. For $\mathrm{C}^{\bullet} \mathrm{H}_{2} \mathrm{CH}(\mathrm{OH}) \mathrm{CH}_{3}$, there are two $\mathrm{H}_{0}-\mathrm{CH}_{2}$ gauche conformers and one $\mathrm{H}_{0}-\mathrm{CH}_{2}$ anti conformer. The energy for the $\mathrm{H}_{0}-\mathrm{CH}_{2}$ anti conformer is $1.16 \mathrm{kcal} / \mathrm{mol}$ higher than that of $\mathrm{H}_{0}-\mathrm{CH}_{2}$ gauche conformer. For $\mathrm{C}^{\bullet} \mathrm{H}_{2} \mathrm{CCl}(\mathrm{OH}) \mathrm{CH}_{3}$, the $\mathrm{H}_{0}-\mathrm{CH}_{2}$ gauche conformer is 0.29 $\mathrm{kcal} / \mathrm{mol}$ higher than that of the $\mathrm{H}_{0}-\mathrm{CH}_{2}$ anti conformer. The maxima on the potential curves of $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CClOH}$ and $\mathrm{C}^{\circ} \mathrm{H}_{2} \mathrm{CCl}(\mathrm{OH}) \mathrm{CH}_{3}$ correspond to the structures where the hydroxyl H atom is anti to the Cl atom on the $\alpha$-carbon due to anomeric effects. This phenomenon is similar to those in the chloromethanol and chloroethanol observed in the previous study. ${ }^{46,59}$

### 2.4.3 Enthalpy of Formation

The total electronic energies are determined at the B3LYP/6-31G(d,p), B3LYP/6$311+G(3 \mathrm{df}, 2 \mathrm{p})$ and $\mathrm{CBSQ} / / \mathrm{B} 3 \mathrm{LYP} / 6-31 \mathrm{G}(\mathrm{d}, \mathrm{p})$ levels for chloropropanol and corresponding radicals. The spin expectation values, $\left\langle\mathrm{S}^{2}\right\rangle$, range from 0.760 to 0.786 for the target radicals, and suggest no significant error for pure doublet radicals due to spin contamination.

The $\Delta H_{f}{ }^{0}{ }_{298}$ values are estimated using total energies and isodesmic reactions. The accuracy of the enthalpies of formation obtained theoretically is controlled by several
factors: the level of sophistication applied to calculate the electronic energy, the reliability of the $\Delta H_{\mathrm{f}}^{\mathrm{o}} 298$ of the reference compounds, the uncertainty of the ZPVEs and the thermal corrections, and the choice of the isodesmic reactions. The uncertainty of ZPVEs and thermal correction are small relative to other errors. Scott and Radom ${ }^{42}$ report rms errors $\pm 0.1 \mathrm{kcal} / \mathrm{mol}$ for ZPVE after scaling 0.9806 for B3LYP/6-31G(d) and rms errors of $\pm 0.01 \mathrm{kcal} / \mathrm{mol}$ for thermal correction from 0 to 298 K in DFT. We assume that the uncertainty from ZPVEs and the thermal correction in our calculation have the same error ranges and assign the cumulative ZPVEs and the thermal energy uncertainties to be $0.44 \mathrm{kcal} / \mathrm{mol}$ in an isodesmic reaction. The reaction enthalpies and $\Delta H_{\mathrm{f} 298}^{0}$ values for 6 target species obtained from 8 isodesmic reactions are tabulated in Table A.4. The results for $\Delta H_{\mathrm{f}}^{\mathrm{o}} 298$ values in Table A. 4 show good consistency for 6 target species over eight working reactions and the three calculation methods. DFT calculations show good agreement with the high level ab initio calculations, indicating the errors inherent in computations for different types of molecule are canceled to a significant extent and lead to reliable results. Ab initio calculations show remarkable consistency at the CBSQ//B3 level where the standard deviation is within $0.3 \mathrm{kcal} / \mathrm{mol}$. The $\Delta H_{\mathrm{f}}{ }^{0} 298$ values for target radicals are based on the $\Delta H_{\mathrm{f}}^{\mathrm{o}} 298$ values of the parent molecules in this work. The calculated $\Delta H_{\mathrm{f}}^{\mathrm{o}} 298$ for $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CHOH}$ in this work is $-69.19 \mathrm{kal} / \mathrm{mol}$, which is similar to the results of Atkinson et al., ${ }^{69}-65.15$; Frenkel et al., ${ }^{50}-65.18$, Snelson et al., ${ }^{70}-65.19$, and Cohen, ${ }^{71}-65.20 \mathrm{kal} / \mathrm{mol}$. The $\Delta H_{\mathrm{f}}{ }^{\mathrm{o}}{ }_{298}$ for $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CHO}^{\bullet}$ are calculated to be -11.87 $\mathrm{kal} / \mathrm{mol}$ at the $\mathrm{CBSQ} / / \mathrm{B} 3$ level, which shows agreement with Ramond et al.'s value, $11.0 \pm 1.2 \mathrm{kcal} / \mathrm{mol},{ }^{68}$ which derived from the $\Delta H_{\mathrm{f}}{ }^{\mathrm{o}} 298$ of $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CHOH}$ and electron affinities.

The recommended $\Delta H_{\mathrm{f}_{2}}^{\mathrm{o}}$. for $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CHOH},\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CHO}^{\bullet}, \mathrm{C}^{\bullet} \mathrm{H}_{2}\left(\mathrm{CH}_{3}\right) \mathrm{CHOH}$, $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CClOH},\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CClO}$ and $\mathrm{C}^{\circ} \mathrm{H}_{2} \mathrm{CCl}(\mathrm{OH}) \mathrm{CH}_{3}$ are $-69.19 \pm 2.2,-11.85 \pm 1.9,-$ $14.95 \pm 2.8,-79.83 \pm 2.1,-25.88 \pm 2.0$, and $-29.00 \pm 2.8 \mathrm{kcal} / \mathrm{mol}$, respectively, which are the average values from eight reactions for each species at the CBSQ//B3 calculation level, where the statistical distribution of rotational conformers is included.

The $\mathrm{RO}-\mathrm{H}, \mathrm{R}-\mathrm{OH}, \mathrm{R}-\mathrm{H}$ and $\mathrm{R}-\mathrm{Cl}$ bond dissociation energies in Table 2.8 were calculated using the $\Delta H_{\mathrm{f}}{ }^{\circ} 298$ values and the $\Delta H_{\mathrm{f}}^{\circ} 298$ of reference radicals. These bond energies are very similar to those derived from chloromethanol and $\alpha$-chloroethanol in previous work, ${ }^{46,59}$ and a comparison for these bond energies derived from monochloroalcohols is listed in Table 2.9. Bond energies on isopropanol for the methyl hydrogens are $102 \mathrm{kcal} / \mathrm{mol}$, and the hydroxyl hydrogen bond energy is $105 \mathrm{kcal} / \mathrm{mol}$. Bond energies in 2-chloro-2-propanol are $103 \mathrm{kcal} / \mathrm{mol}$ for the methyl hydrogens and $106 \mathrm{kcal} / \mathrm{mol}$ for the hydroxyl hydrogen.

### 2.4.4 Entropy and Heat Capacity

The $S^{\circ}{ }_{298}$ and $C_{p}(T)$ 's ( $300 \leq \mathrm{T} / \mathrm{K} \leq 1500$ ) calculation results using the B3LYP/6$31 \mathrm{G}(\mathrm{d}, \mathrm{p})$ geometries and harmonic frequencies are summarized in Table 2.9. The torsion frequencies are omitted in the calculation of $S_{298}^{0}$ and $C_{p}(\mathrm{~T})$; but we replace their contributions with values from analysis of the internal rotations. TVR, represents the sum of the contributions from translation, vibration and external rotation for $S^{\circ}{ }_{298}$ and $C_{p}(T)$ 's and was calculated using the program "SMCPS". ${ }^{72}$ I. R., represents the contributions from hindered internal rotations about $\mathrm{C}-\mathrm{C}$ and $\mathrm{C}-\mathrm{O}$ bonds for $S^{0}{ }_{298}$ and $C_{p}(T)$ and was calculated by the program "ROTATOR"."

This calculation is based on an optimized 3D atom coordinate for the lowest energy conformer, the respective connection to atoms of the bond about which rotation is occurring, and the coefficients of the Fourier expansion components from rotational potential curves.

The $\mathrm{C}^{\bullet} \mathrm{H}_{2} \mathrm{CH}(\mathrm{OH}) \mathrm{CH}_{3}$ and $\mathrm{C}^{\bullet} \mathrm{H}_{2} \mathrm{CCl}(\mathrm{OH}) \mathrm{CH}_{3}$ radicals have an optical isomer number of two due to the different constituents on the central carbon. The thermochemical properties of 2-propanol in Table 2.9 show agreement with the values
calculated by Chao ${ }^{50}$ at TRC using the methods of statistical thermodynamics based on spectral data.

${ }^{\mathrm{a}}$ Thermodynamic properties are referred to a standard state of an ideal gas of at 1 atm . ${ }^{\mathrm{b}}$ Units in $\mathrm{kcal} / \mathrm{mol}$. ${ }^{\mathrm{c}}$ Units in $\mathrm{cal} / \mathrm{mol} / \mathrm{K}$. ${ }^{\mathrm{d}}$ The sum of contributions from translations, vibrations, and external rotations. ${ }^{e}$ Contribution from internal rotation about the $\mathrm{C}-\mathrm{C}$ bond. ${ }^{\mathrm{f}}$ Contribution from internal rotation about the C - O bond. ${ }^{\mathrm{g}}$ Symmetry number is taken into account (-Rln(symmetry number)). ${ }^{\mathrm{h}}$ Symmetry number. ${ }^{\text {i }}$ Optical isomer number. $-\mathrm{CH}_{2}$ group is not planar, and the standard entropies include the entropy of mixing of rotational conformations or optical conformations.

### 2.4.5 Relative Stability of the Alkyl and Alkoxy Radicals

The $\mathrm{C}-\mathrm{Cl}$ bond is usually ca. $10 \mathrm{kcal} / \mathrm{mol}$ weaker than the $\mathrm{C}-\mathrm{C}$ or $\mathrm{C}-\mathrm{H}$ bonds and this should lead to interesting stabilities for the intermediate chloro-radicals in the atmosphere. Reaction scheme 1 shows the $\Delta H^{0}{ }_{\mathrm{rxn}}$ and $\mathrm{E}_{\mathrm{a}}$ for the two non-chlorinated alkyl radicals undergoing $\beta$-scission to eliminate a methyl or an OH radical; the isopropoxy radical dissociation to $\mathrm{CH}_{3} \mathrm{CHO}$ and methyl has a lower $\Delta H^{\circ}{ }_{\mathrm{rxn}}$ value with the transition state lying $13.22 \mathrm{kcal} / \mathrm{mol}$ above $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CHO}^{\circ}$ calculated at the $\mathrm{CBSQ} / / \mathrm{B} 3$ level.

## Reaction Scheme 1

$\mathrm{C}^{\bullet} \mathrm{H}_{2} \mathrm{CH}(\mathrm{OH}) \mathrm{CH}_{3} \rightarrow \mathrm{CH}_{2}=\mathrm{CHCH}_{3}+\mathrm{OH}^{\bullet}$

$$
\mathrm{C}^{\bullet} \mathrm{H}_{2} \mathrm{CH}(\mathrm{OH}) \mathrm{CH}_{3} \rightarrow \text { syn }-\mathrm{CH}_{2}=\mathrm{CHOH}+\mathrm{CH}_{3}{ }^{\bullet}
$$

$\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CHO}^{\bullet} \rightarrow \mathrm{CH}_{3} \mathrm{CHO}+\mathrm{CH}_{3}{ }^{\bullet}$

$$
\Delta H_{\mathrm{rxn}}^{0}(\mathrm{kcal} / \mathrm{mol}) \quad \mathrm{E}_{\mathrm{a}}(\mathrm{kcal} / \mathrm{mol})
$$

$$
28.62
$$

19.18
29.02 (CBSQ)
6.97
13.22 (CBSQ)

Reaction scheme 2 shows the $\Delta H_{\mathrm{rxn}}^{0}$ and $\mathrm{E}_{\mathrm{a}}$ for Cl elimination from one secondary chlorocarbon radical where $\Delta H_{\mathrm{rxn}}^{0}$ is $18 \mathrm{kcal} / \mathrm{mol}$, but the chloro-isopropoxy radical has a similar bond strength for $\mathrm{C}-\mathrm{Cl}$ and $\mathrm{C}-\mathrm{CH}_{3}$.

## Reaction Scheme 2

|  | $\Delta H_{\mathrm{rxn}}^{\circ}(\mathrm{kcal} / \mathrm{mol})$ | $\mathrm{E}_{\mathrm{a}}(\mathrm{kcal} / \mathrm{mol})$ |
| :--- | :---: | :--- |
| $\mathrm{C}^{\bullet} \mathrm{H}_{2} \mathrm{CCl}(\mathrm{OH}) \mathrm{CH}_{3} \rightarrow \mathrm{CH}_{2}=\mathrm{C}(\mathrm{OH}) \mathrm{CH}_{3}+\mathrm{Cl}^{\bullet}$ | 18.01 | 18.01 |
| $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CClO} \rightarrow \mathrm{CH}_{3} \mathrm{COCH}_{3}+\mathrm{Cl}^{\bullet}$ | 2.57 | 2.57 |
| $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CClO}^{\bullet} \rightarrow \mathrm{CH}_{3} \mathrm{C}(\mathrm{O}) \mathrm{Cl}+\mathrm{CH}_{3}^{\bullet}$ | 2.67 | $10.75(\mathrm{CBSQ})$ |

The alkyl-alkoxy and chloroalkoxy radical systems are both unstable with short atmospheric lifetimes. We note that there is no barrier (above the $\Delta H_{r \times n}^{0}$ ) for the Cl elimination reaction of $\mathrm{C}^{\bullet} \mathrm{H}_{2} \mathrm{CCl}(\mathrm{OH}) \mathrm{CH}_{3}$ and its half-life at 298 K can be qualitatively
estimated to be $\sim 1.1 \mathrm{~s}$; which is sufficient time for the radical to undergo association with $\mathrm{O}_{2}$ under atmospheric and low temperature combustion conditions. Wu and Carr ${ }^{74,75}$ reported the lifetime for $\mathrm{CH}_{2} \mathrm{ClO}^{\bullet}$ is less than 1 ms . Hou et al. ${ }^{63}$ reported that the threecenter elimination of HCl is the most favorable channel for $\mathrm{CH}_{3} \mathrm{CHClO}^{\circ}$ decomposition, and estimated the lifetime of $\mathrm{CH}_{3} \mathrm{CHClO}^{\circ}$ under the typical tropospheric condition to be $3.3 \mu \mathrm{~s}$. The stability of these chloroalkoxy radicals is low, but these intermediate radicals are formed by $\mathrm{OH}^{\bullet}$ radical addition to chloro-olefins in the atmosphere and by $\mathrm{OH}^{\bullet}, \mathrm{O}^{\bullet}$, and $\mathrm{HO}_{2}{ }^{\bullet}$ addition to unsaturated chlorocarbons in combustion environments. The thermochemical properties of these radicals are important in describing the reaction paths and the products of the first and second dissociation reactions.

### 2.4.6 Group Additivity Values and HBI Group Values

The $\mathrm{C} / \mathrm{C}_{2} / \mathrm{Cl} / \mathrm{O}$ group value in Table 2.12 was derived from the thermodynamic property data of $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CClOH}$. The group values for $\Delta H_{\mathrm{f}}^{0} 298$ and $C_{p}(T)$ of $\mathrm{C} / \mathrm{C}_{2} / \mathrm{Cl} / \mathrm{O}$ were calculated on the basis of the reaction:

$$
\left(\mathrm{CH}_{3} \mathrm{CCl}(\mathrm{OH}) \mathrm{CH}_{3}\right)=\left(\mathrm{C} / \mathrm{C}_{2} / \mathrm{Cl} / \mathrm{O}\right)+2\left(\mathrm{C} / \mathrm{C} / \mathrm{H}_{3}\right)+(\mathrm{O} / \mathrm{C} / \mathrm{H})
$$

and $\mathrm{S}^{0}{ }_{298}$ of $\mathrm{C} / \mathrm{C}_{2} / \mathrm{Cl} / \mathrm{O}$ was calculated by considering symmetry correction:

$$
\left(\mathrm{CH}_{3} \mathrm{CCl}(\mathrm{OH}) \mathrm{CH}_{3}\right)=\left(\mathrm{C} / \mathrm{C}_{2} / \mathrm{Cl} / \mathrm{O}\right)+2\left(\mathrm{C} / \mathrm{C} / \mathrm{H}_{3}\right)+(\mathrm{O} / \mathrm{C} / \mathrm{H})-\mathrm{R} \ln (\sigma)
$$

where $\mathrm{R}=1.987 \mathrm{cal} / \mathrm{mol} \mathrm{K}, \sigma$ stands for symmetry number. The thermochemical properties for the $\mathrm{C} / \mathrm{C} / \mathrm{H}_{3}$ and $\mathrm{O} / \mathrm{C} / \mathrm{H}$ groups were taken from the literature. ${ }^{65} \Delta H_{\mathrm{f}}{ }^{\mathrm{o}} 298$ in the HBI implementation group is the bond enthalpy of $\mathrm{R}-\mathrm{H}$ cleavage reaction at the indicated site. $\Delta S^{0}{ }_{298}$ and $\Delta C_{p}(T)$ in HBI groups are the differences in respective properties of the molecule and the radical; such that when HBI increment groups for
$\Delta S^{0}{ }_{298}$ and $\Delta C_{p}(T)$ are added to the parent, the result is the corresponding value for the radical.

Table 2.12 Central Group and HBI Group Values

${ }^{\mathrm{a}} \mathrm{H}$ atoms are assumed to fill in carbon. ${ }^{\mathrm{a}}$ Units in $\mathrm{kcal} / \mathrm{mol}$. ${ }^{\mathrm{b}}$ Units in cal/mol-K.

Entropy values are intrinsic, i.e., the correction for spin degeneracy of the electronic state and gain and loss of an optical isomer are included when appropriate, but symmetry for either parent or radical is not included in HBI groups. Table 2.12 lists chloro-oxy-alkyl central group data from mono, di, and tri-carbon chloro-alcohols by this work and previous work. ${ }^{46,59}$ The HBI group values for $\mathrm{C}_{2} \mathrm{CO}^{\bullet}, \mathrm{C}_{2} \mathrm{CClO}^{\bullet}, \mathrm{C}^{\bullet} \mathrm{C}(\mathrm{OH}) \mathrm{C}$, and $\mathrm{C}^{\bullet} \mathrm{CCl}(\mathrm{OH}) \mathrm{C}$ derived from this chapter are also listed in Table 2.12 for comparison with other HBI groups from $\mathrm{C}_{1}-\mathrm{C}_{2}$ chloro-alcohols. ${ }^{46,59}$ It can be seen from Table 2.12 that the enthalpy and heat capacity for HBI groups with similar chemical environments are similar; this suggests that these HBI groups can be used to predict accurate thermochemical properties of other radicals with similar chemical environments. The entropies are however slightly different even in the same series.

For example, in the alkoxy series, the HBI values for the entropy of $\mathrm{CH}_{3} \mathrm{O}^{\bullet}$, $\mathrm{CCO}^{\bullet}, \mathrm{C}_{2} \mathrm{CO}^{\bullet}$ are $-2.80,-0.90,-1.90 \mathrm{cal} / \mathrm{mol} . \mathrm{K}$ respectively, while bond energies and heat capacities remain similar. This is a result of the nature of intrinsic entropy in the different molecules. A complete set of recommended HBI values with average entropy for use in general group additivity applications is listed in Table 2.13.

### 2.5 Chlorinated Ethyl Hydroperoxides and Radicals

### 2.5.1 Geometries

The fully optimized geometric parameters along with vibrational frequencies and moments of inertia calculated at the B3LYP/6-31G(d,p) level for the three chlorinated ethyl hydroperoxides are presented in Appendix (Table A.5). The calculation at the B3LYP/6-31G(d,p) level gives $\mathrm{O}-\mathrm{O}$ bond length $1.45 \AA$ in all three chlorinated ethyl hydroperoxides, which is in good agreement with the experimental data ( $1.452 \AA$ for $\mathrm{H}_{2} \mathrm{O}_{2}$ ) of Khachkuruzov and Przhevalskii ${ }^{76}$ using IR spectroscopy.

Effects of chlorine $\beta$-substitution on molecular geometries can be seen from Table A.5. The $\mathrm{C}-\mathrm{C}$ bond lengths for $\beta$-chloroethyl hydroperoxides are increased with the increased chlorine substitution, but the $\mathrm{C}-\mathrm{O}$ bond lengths decrease with the increased chlorine substitution. This is because the Cl atom withdraws the electrons through its inductive effect; the lone pairs from the peroxy oxygen are oriented towards the $-\mathrm{CH}_{2}-$ group, making the $\mathrm{C}-\mathrm{O}$ bond length shorter than the normal $\mathrm{C}-\mathrm{O}$ bond.

Table 2.14 Effects of Chlorine $\beta$-Substitution on Bond Length

| Species | $\mathrm{C}-\mathrm{C}(\AA)$ | $\mathrm{C}-\mathrm{O}(\AA)$ | $\mathrm{O}-\mathrm{H}(\AA)$ |
| :--- | :---: | :---: | :---: |
| $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OOH}$ | 1.5227 | 1.4266 | 0.9707 |
| $\mathrm{CH}_{2} \mathrm{ClCH}_{2} \mathrm{OOH}$ | 1.5218 | 1.4213 | 0.9735 |
| $\mathrm{CHCl}_{2} \mathrm{CH}_{2} \mathrm{OOH}$ | 1.5317 | 1.4113 | 0.9728 |
| $\mathrm{CCl}_{3} \mathrm{CH}_{2} \mathrm{OOH}$ | 1.5458 | 1.4071 | 0.9727 |

As illustrated in Table A.5, the lowest energy conformation for the three chlorinated ethyl hydroperoxides has the -OOH group gauche to the maximum number of chlorine atoms, despite the apparent steric penalty incurred. This is because the gauche orientation of the peroxy group allows for intramolecular interaction between the peroxy H atom and a Cl atom on the chloroethyl group. The inter-atomic distances
between the peroxy H atom and a Cl atom in the chloroethyl group for $\mathrm{CH}_{2} \mathrm{ClCH}_{2} \mathrm{OOH}$, $\mathrm{CHCl}_{2} \mathrm{CH}_{2} \mathrm{OOH}$, and $\mathrm{CCl}_{3} \mathrm{CH}_{2} \mathrm{OOH}$ are 2.642, 2.742, and $2.751 \AA$, respectively. These distances provide an indication to the degree of intramolecular hydrogen bonding present in these species.

Hydrogen bonding can occur when the distance between a hydrogen atom and an electronegative donor is significantly less the sum of the van der Waals radii. The van der Waals radii are $1.2 \AA$ and $1.8 \AA$ for H and Cl atoms, respectively. ${ }^{47}$ Due to the intramolecular hydrogen bonding between the peroxy H atom and a Cl atom, the $\mathrm{O}-\mathrm{H}$ bond lengths for the three $\beta$-chloroethyl hydroperoxides increase $0.03 \AA$ relative to
normal $\mathrm{O}-\mathrm{H}$ bond in $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OOH}$. This hydrogen bonding results in an increase in the $\mathrm{O}-\mathrm{H}$ bond strength by ca. $2 \mathrm{kcal} / \mathrm{mol}$ (as shown in Table 2.15). Additional chlorine substitutions on the ethyl hydroperoxides slightly decrease the $\mathrm{O}-\mathrm{H}$ bond lengths 0.007 $\sim 0.008 \AA$, and increase the $\mathrm{O}-\mathrm{H}$ bond strength by $1.2 \mathrm{kcal} / \mathrm{mol}$. These $\mathrm{O}-\mathrm{H}$ bond length decreases coincide with the increased inter-atomic $\mathrm{H} \cdots \mathrm{Cl}$ distances, which are due to the increased repulsion between the electronegative O and Cl atoms.

### 2.5.2 Rotational Barriers

Potential energy as function of torsion angle is determined by scanning the dihedral angles from $0^{\circ}$ to $360^{\circ}$ at $15^{\circ}$ increments and allowing the remaining molecular structural parameters to be optimized at the B3LYP/6-31G(d,p) level. The barrier of a given rotation is then calculated as the difference between the highest points on the potential energy surface and the corresponding most stable conformer. The geometries at the points of minima and maxima are fully optimized. The calculated rotational barriers about the $\mathrm{C}-\mathrm{C}, \mathrm{C}-\mathrm{O}$, and $\mathrm{O}-\mathrm{O}$ bonds of the 3 chlorinated ethylhydroperoxides are shown in Figures 2.9, 2.10, and 2.11, respectively.

The calculated rotational barriers about the $\mathrm{C}-\mathrm{C}$ bond of the three target species are shown in Figure 2.9. All three curves show three minima and three maxima with barriers between 4.77 and $5.74 \mathrm{kcal} / \mathrm{mol}$; the curve for $\mathrm{CCl}_{3}-\mathrm{CH}_{2} \mathrm{OOH}$ shows 3-fold symmetry. These curves represent typical C-C bond rotational potentials, in which the eclipsed structures are corresponding to the maxima and the staggered structures are corresponding to the minima on the potential curves.

Figure 2.9 Potential barriers for internal rotation about the $\mathrm{C}-\mathrm{C}$ bond of $\mathrm{CH}_{2} \mathrm{ClCH}_{2} \mathrm{OOH}, \mathrm{CHCl}_{2} \mathrm{CH}_{2} \mathrm{OOH}$, and $\mathrm{CCl}_{3} \mathrm{CH}_{2} \mathrm{OOH}$.

Figure 2.10 shows the potential curves for rotational barriers about the $\mathrm{C}-\mathrm{O}$ bond for three chloroethyl hydroperoxides. The conformers with dihedral $\angle \mathrm{C}-\mathrm{C}-\mathrm{O}-\mathrm{O} \approx$ $90^{\circ}$ are most stable because of two electrostatic interactions. The first is the $\mathrm{O} \cdots \mathrm{H}$ interaction between the peroxy O atom and the H atom in the $-\mathrm{CH}_{2}$ - group, and the interatomic distance between them is $2.37 \AA$, which is significantly less than the sum of the van der Waals radii for O and H atoms $(2.70 \AA)$. The second is the $\mathrm{H} \cdots \mathrm{Cl}$ interaction between the peroxy H atom and the Cl atom in the chloroethyl group, and the interatomic distance is $2.63 \AA$ that is less than the sum of the van der Waals radii of H and Cl $(3.0 \AA) .{ }^{47}$ The conformers with dihedral $\angle \mathrm{C}-\mathrm{C}-\mathrm{O}-\mathrm{O} \approx 180^{\circ}$ or $270^{\circ}$ do not have the second $\mathrm{H} \cdots \mathrm{Cl}$ interactions, so they have $0.63 \sim 2.47 \mathrm{kcal} / \mathrm{mol}$ higher energy than the lowest energy conformers. The highest rotational barriers about the $\mathrm{C}-\mathrm{O}$ bond are $7.2 \sim$ $9.7 \mathrm{kcal} / \mathrm{mol}$, corresponding to the $\mathrm{OH}-\mathrm{CCl}_{\mathrm{x}}(\mathrm{x}=1 \sim 3)$ eclipsed structures.

Figure 2.10 Potential barriers for internal rotation about the $\mathrm{C}-\mathrm{O}$ bond of $\mathrm{CH}_{2} \mathrm{ClCH}_{2} \mathrm{OOH}, \mathrm{CHCl}_{2} \mathrm{CH}_{2} \mathrm{OOH}$, and $\mathrm{CCl}_{3} \mathrm{CH}_{2} \mathrm{OOH}$

Figure 2.11 Potential barriers for internal rotation about the $\mathrm{O}-\mathrm{O}$ bond of $\mathrm{CH}_{2} \mathrm{ClCH}_{2} \mathrm{OOH}, \mathrm{CHCl}_{2} \mathrm{CH}_{2} \mathrm{OOH}$, and $\mathrm{CCl}_{3} \mathrm{CH}_{2} \mathrm{OOH}$.

Figure 2.11 shows calculated rotational barriers about the $\mathrm{O}-\mathrm{O}$ bond of the three chlorinated ethyl hydroperoxides. The $\mathrm{HO}-\mathrm{OCCCl}_{\mathrm{x}}(\mathrm{x}=1 \sim 3)$ eclipsed structures for the three chlorinated ethyl hydroperoxides correspond to the highest rotational barriers, because the four non-bonding electron pairs on peroxy oxygen atoms eclipse to each other. While the conformers with the four non-bonding electron pairs on the peroxy oxygen atoms staggered to each other and with the nearest interatomic distances between the peroxy H atom and the Cl atom correspond to the most stable conformers.

### 2.5.3 Enthalpy of Formation

The $\Delta H_{\mathrm{f}}^{\mathrm{o}} 298$ values are calculated using total energies and working isodesmic reactions. The reaction enthalpies and $\Delta H_{\mathrm{f}}^{\mathrm{o}} 298$ values for three stable species obtained from three isodesmic reactions are tabulated in Table 2.16, and the $\Delta H_{\mathrm{f}}{ }^{0} 298$ values of corresponding radicals are tabulated in Table A.4. The results for $\Delta H_{\mathrm{f}}^{\mathrm{o}}{ }_{298}$ values in Table 4 show good consistency for the 3 chloroethyl hydroperoxides over 3 isodesmic reactions and the four calculation methods. The DFT calculations show good agreement with the high level $a b$ initio calculations, indicating the errors inherent in computations for different types of molecule are canceled to a significant extent and lead to reliable results.

The calculated $\Delta H_{\mathrm{f}}{ }^{\mathrm{o}} 298$ values in Table 2.16 and Table A. 5 are the enthalpy values for pure enantiomer of the lowest energy. The recommended $\Delta H_{\mathrm{f}}^{\mathrm{o}} 298$ values for $\mathrm{CH}_{2} \mathrm{ClCH}_{2} \mathrm{OOH}, \mathrm{CHCl}_{2} \mathrm{CH}_{2} \mathrm{OOH}$, and $\mathrm{CCl}_{3} \mathrm{CH}_{2} \mathrm{OOH}$ are $-45.47 \pm 1.20,-48.92 \pm 1.50$ and $-50.21 \pm 1.36 \mathrm{kcal} / \mathrm{mol}$, respectively. Here the statistical distribution of rotational conformers are considered and calculated by $\Delta H_{\mathrm{f}}^{\mathrm{o}}{ }_{\text {mix }}=\mathrm{n}_{\mathrm{i}} \Delta H_{\mathrm{f}}{ }^{\mathrm{o}}$, where $\mathrm{n}_{i}$ and $\Delta H_{\mathrm{f}}{ }^{\mathrm{o}}$ i are the Boltzmann equilibrium mole fraction and the enthalpy of formation of the $i$ th conformer.

Manion ${ }^{79}$ in an extensive review, compared ab initio calculated values and experimental results on the relative $\Delta H_{\mathrm{f}}^{\mathrm{o}} 298$ 's of the isomeric chlorinated $\mathrm{C}_{2}$ compounds with two to four chlorine atoms. He reports the theory and experiment are in good agreement with a largest deviation of $0.79 \mathrm{kcal} / \mathrm{mol}$. Based on this comparison, our calculated $\Delta H_{\mathrm{f}}^{\mathrm{o}} 298$ values for the three chlorinated ethyl hydroperoxides should have similar accuracy.

### 2.5.4 Entropy and Heat Capacity

The $S^{0}{ }_{298}$ and $C_{p}(T)$ 's ( $300 \leq \mathrm{T} / \mathrm{K} \leq 1500$ ) for three chlorinated ethylhydroperoxides using the geometries and harmonic frequencies determined at the B3LYP/6-31G(d,p) level are summarized in Table 2.17. The torsion frequencies, corresponding to the $\mathrm{C}-\mathrm{C}, \mathrm{C}-\mathrm{O}$, and $\mathrm{O}-\mathrm{O}$ bond rotations, are omitted in calculation of $S^{\circ}{ }_{298}$ and $C_{p}(T)$ 's; but we replace their contributions with values from analysis of the internal rotations. TVR, represent the sum of the contributions from translation, vibration and external rotation to $S^{0}{ }_{298}$ and
$C_{p}(T)$ 's obtained by statistical mechanics. I.R., represent the contributions from hindered internal rotations about the $\mathrm{C}-\mathrm{C}, \mathrm{C}-\mathrm{O}$ and $\mathrm{O}-\mathrm{O}$ bonds to $S^{\mathrm{o}}{ }_{298}$ and $C_{p}(T)$ 's.

${ }^{\mathrm{b}}$ Units in $\mathrm{kcal} / \mathrm{mol}$. ${ }^{\mathrm{c}}$ Units in $\mathrm{cal} / \mathrm{mol} / \mathrm{K}$. ${ }^{\mathrm{d}}$ The sum of contributions from translations, vibrations, and external rotations. ${ }^{e}$ Contribution from internal rotation about the $\mathrm{C}-\mathrm{C}$ bond. ${ }^{\mathrm{f}}$ Contribution from internal rotation about the $\mathrm{C}-\mathrm{O}$ bond. ${ }^{\mathrm{g}}$ Contribution from internal rotation about the $\mathrm{O}-\mathrm{O}$ bond. ${ }^{\mathrm{h}}$ Symmetry number. ${ }^{i}$ Optical isomer number.

### 2.5.5 Group Additivity Correction Terms

Group additivity ${ }^{64}$ is a straightforward and reasonably accurate calculation method to estimate thermodynamic properties of hydrocarbons and oxygenated hydrocarbons; but conventional group additivity does not work well for chlorocarbons or other halocarbons, as group additivity does not incorporate effects of next nearest neighbors. ${ }^{80}$ In this chapter, three sets of peroxy oxygen -- chlorine interaction terms are defined to be used with Benson type group additivity scheme for calculation of the thermodynamic properties of multichloro peroxy-hydrocarbons.

In the three chlorinated ethyl hydroperoxides, the nearest inter-atomic distances between the Cl atom and the O atom are $3.10 \sim 3.23 \AA$, so there are significant interactions between the electronegative Cl and the O atoms. The interaction values between chlorine(s) on the ethyl and the peroxy oxygen $\left(\mathrm{OO} / \mathrm{Cl}, \mathrm{OO} / \mathrm{Cl}_{2}\right.$, and $\left.\mathrm{OO} / \mathrm{Cl}_{3}\right)$ are calculated from differences between the sum of defined chlorinated ethyl hydroperoxides group values and the determined thermodynamic properties of the parent compounds. The calculated interaction values are listed in Table 2.18.

Table 2.18 Thermodynamic Properties of Peroxy-Chlorine(s) Interaction Group

|  |  |  |  |  |  |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| interaction group | $\Delta H_{\mathrm{f} 298}^{\mathrm{o}}$ | $S_{298}^{\mathrm{b}}$ | $C_{p} 300^{\mathrm{b}}$ | $C_{p} 400$ | $C_{p} 500$ | $C_{p} 600$ | $C_{p} 800$ | $C_{p} 1000$ |
| $\mathrm{INT} / \mathrm{OO} / \mathrm{Cl}$ | 2.72 | 3.20 | 1.15 | 0.88 | 0.46 | -0.31 | -0.85 | -1.55 |
| $\mathrm{INT} / \mathrm{OO} / \mathrm{Cl}_{2}$ | 3.51 | -0.45 | 2.77 | 2.47 | 1.68 | 0.61 | -0.40 | -1.17 |
| $\mathrm{INT} / \mathrm{OO} / \mathrm{Cl}_{3}$ | 5.02 | 0.48 | 1.95 | 1.43 | 0.61 | -0.39 | -1.17 | -1.67 |

${ }^{2}$ Units in $\mathrm{kcal} / \mathrm{mol}$. ${ }^{\mathrm{b}}$ Units in $\mathrm{cal} / \mathrm{mol} / \mathrm{K}$.

The interaction values in Table 2.18 indicate a several $\mathrm{kcal} / \mathrm{mol}$ increase in enthalpy due to destabilizing interaction of chlorine(s) on the ethyl group with the peroxy group. The group additivity corrections for the $\Delta H_{\mathrm{f}}{ }^{\mathrm{o}}{ }^{9}$ are $2.72,3.51$, and $5.02 \mathrm{kcal} / \mathrm{mol}$ for the interaction group $\mathrm{OO} / \mathrm{Cl}, \mathrm{OO} / \mathrm{Cl}_{2}$, and $\mathrm{OO} / \mathrm{Cl}_{3}$, respectively. Interaction terms for entropies at 298 K and heat capacities listed in Table 2.18 are relatively small.

### 2.6 Summary

Structures and thermochemical properties on chlorinated alcohols, chlorinated hydroperoxides and corresponding alkoxy, hydroxy alkyl radicals, peroxy and hydroperoxy alkyl radicals are determined by $a b$ initio and density functional calculations. Molecular structures and vibration frequencies are determined at the

B3LYP/6-31G(d,p) density functional level, with single point calculations for the energy at the B3LYP/6-311+G(3df,2p), QCISD(T)/6-31G(d,p) and CBSQ//B3LYP/6-31G(d,p) levels. The $S_{298}^{0}$ and $C_{p}(T)$ 's ( $300 \leq T / \mathrm{K} \leq 1500$ ) from vibrational, translational, and external rotational contributions are calculated using the rigid-rotor-harmonic-oscillator approximation based on the vibration frequencies and structures obtained from the density functional study. Potential barriers for the internal rotations are calculated at the B3LYP/6-31G(d,p) level, and hindered rotational contributions to $S^{0}{ }_{298}$ and $C_{p}(T)$ 's are calculated by using direct integration over energy levels of the internal rotational potentials. The values of $\Delta H_{\mathrm{f}}{ }^{0} 298$ are determined using isodesmic reactions with group balance if possible. Groups for use in Benson type additivity estimations are determined for the carbon bonded to oxygen and chlorine(s). Hydrogen bond increment groups for the chloroalkoxy, hydroxy chloroalkyl radicals and interaction terms for peroxy group with chlorine(s) on a $\beta$ carbon are developed for group additivity approach.

## CHAPTER 3

## KINETIC ANALYSIS ON OH ASSOCIATION WITH CHLOROMETHYL RADICAL AND DISSOCIATION OF CHLOROMETHANOL

### 3.1 Background

Oxygenated chloro-hydrocarbons play an important role in both industrial and environmental chemistry. The chemical activation reactions of $\mathrm{CH}_{2} \mathrm{Cl}+\mathrm{OH}$ is considered to be a part of reaction mechanism for the oxidation of chloro-hydrocarbon in combustion and photochemical processes.

Wallington et al. ${ }^{81}$ studied the stability and infrared spectra of mono-, di-, and trichloromethanol prepared by UV irradiation of $\mathrm{CH}_{3} \mathrm{OH} / \mathrm{Cl}_{2} / \mathrm{N}_{2}$ gas mixtures. They observed that the chlorinated methanols decayed with the first-order kinetics to HCl and the corresponding carbonyl compounds, and that the decomposition was heterogeneous since the decay rates increased with increased contact of the chloromethanols with the reactor walls. They reported the upper limit for chlorinated methanols decomposition of $1.05 \times 10^{-2} \mathrm{~s}$.

Wang et al. ${ }^{82}$ studied the unimolecular decomposition of vibrationally exited chloromethanol generated by excited $\mathrm{O}^{*}\left({ }^{1} \mathrm{D}\right)$ inserted in $\mathrm{C}-\mathrm{H}$ bond of $\mathrm{CH}_{3} \mathrm{Cl}$ at the G3(MP2) level, but they did not calculate any reaction rate constant.

Peyerimhoff et al. ${ }^{83}$ investigated photo-fragmentation of chloromethanol along $\mathrm{C}-\mathrm{Cl}$ and $\mathrm{C}-\mathrm{O}$ coordinates using multi-reference single- and double- excitation configuration interaction (MRD-CI) method. They reported that the reactions of $\mathrm{CH}_{2} \mathrm{ClOH} \rightarrow \mathrm{Cl}+\mathrm{CH}_{2} \mathrm{OH}$ and $\mathrm{CH}_{2} \mathrm{ClOH} \rightarrow \mathrm{OH}+\mathrm{CH}_{2} \mathrm{Cl}$ are energetically not preferred
in the ground state, but the reverse reaction (association) is likely and no barrier is found for these formation processes.

The association reactions: $\mathrm{CH}_{2} \mathrm{Cl}+\mathrm{OH}$ and $\mathrm{Cl}+\mathrm{CH}_{2} \mathrm{OH}$ form a chemically activated $\left[\mathrm{CH}_{2} \mathrm{ClOH}\right]^{*}$ adduct, which we show dissociates to $\mathrm{HCl}+\mathrm{CH}_{2} \mathrm{O}$ before it is stabilized. These reactions may serve as a termination reaction in combustion systems and may be a source for conversion of Cl to HCl in the stratosphere. ab initio, density functional, and variational transition state theory (VTST) calculations combined with QRRK theory are preformed in this study to predict the rate constants for association of OH with $\mathrm{CH}_{2} \mathrm{Cl}$ and both the activated and stabilized $\mathrm{CH}_{2} \mathrm{ClOH}$ dissociation kinetics to product channels.

### 3.2 Calculation Method

The geometries of the reactants, intermediates, transition states, and products for $\mathrm{CH}_{2} \mathrm{Cl}+$ OH reaction system are pre-optimized using PM3 in MOPAC program, ${ }^{84}$ followed by optimization and vibrational frequency calculation at the B3LYP/6-31G(d,p) level. The single point energies are calculated at the $\operatorname{QCISD}(\mathrm{T}) / 6-31 \mathrm{G}(\mathrm{d}, \mathrm{p})$ and $\operatorname{CBS}-\mathrm{Q}^{6,40}$ levels using Gaussian98 program. ${ }^{32}$ Vibrational frequencies are scaled by 0.9806 as recommended by Scott et al. ${ }^{42}$ Transition state geometries are identified by the existence of only one imaginary frequency in the normal mode coordinate analysis, evaluation of the TS geometry, and the reaction's coordinate vibration information.

The bimolecular association reaction of $\mathrm{CH}_{2} \mathrm{Cl}+\mathrm{OH}$ does not have a well-defined transition state because of the absence of reaction barrier. To reliably predict this association rate, the flexible variational transition state approach originally developed by

Marcus et al. ${ }^{85-87}$ has been employed by means of VariFlex code ${ }^{88}$ that is aimed at calculating rates at high level of sophistication for barrier-less reactions. The component rates are evaluated at $E$, $J$-resolved level. The energy transfer rate coefficients were computed on the basis of the exponential down model with the $<\Delta \mathrm{E}>$ down value of 230 $\mathrm{cm}^{-1}$. To achieve convergence in the integration over the energy range, an energy grain size of $100 \mathrm{~cm}^{-1}$ is used; this grain size provides numerically converged results for all temperature studies with energy spanning range from $15000 \mathrm{~cm}^{-1}$ below to $44900 \mathrm{~cm}^{-1}$ above the threshold. The total angular momentum J covered the range from 5 to 245 in steps of 10 for the $E, J$-resolved calculation. For loose, barrierless transition state, the Varshni potential: ${ }^{89}$

$$
V=D_{e}\left\{1-\frac{R_{0}}{R} \exp \left[-\beta\left(R^{2}-R_{0}^{2}\right)\right]\right\}^{2}-D_{e}
$$

is employed to represent the potential energy along the individual reaction coordinate. In the above equation, $D_{e}$ is dissociation energy excluding zero-point vibrational energy, where R is the reaction coordinate, i.e., the distance between the two bonding atoms, and $R_{0}$ is the equilibrium value of $R$.

For the dissociation reactions with saddle point transition states, high-pressure limit rate constants $\left(k_{\infty}\right)$ are determined using structural parameters and vibration frequencies from density functional and $a b$ initio calculations and then are fitted by three parameters $A_{\infty}, \mathrm{n}$, and $E_{\mathrm{a}}$ over temperature range from 298 to $2000 \mathrm{~K}: k_{\infty}=A(\mathrm{~T})^{\mathrm{n}} \exp (-$ $E_{a} / \mathrm{RT}$ ). Entropy differences between reactants and TS are used to determine Arrhenius pre-exponential factor via canonical transition state theory ${ }^{12}$ for unimolecular reactions: $\mathrm{A}=(k \mathrm{~T} / h) \exp \left(\Delta \mathrm{S}^{\neq} / \mathrm{R}\right)$. Where $h$ is Plank's constant, $k$ is the Boltzmann constant.

Activation energy is determined as the difference in internal energy between reactant and TS at the CBS-Q level plus the endothermicity of reaction. Branching ratios of the energized adduct to stabilization and product channels are calculated using multifrequency Quantum Rice-Rampsperger-Kassel theory for $k(\mathrm{E})$ combined with master equation analysis for pressure fall-off. ${ }^{26}$

### 3.3 Results and Discussion

### 3.3.1 Potential Energy Surfaces of $\mathbf{C H}_{2} \mathbf{C l}+\mathbf{O H}$

The $\mathrm{CH}_{2} \mathrm{Cl}$ radical association with OH forms the chemically activated $\mathrm{CH}_{2} \mathrm{ClOH}^{*}$ adduct. The reaction channels of the $\mathrm{CH}_{2} \mathrm{ClOH}^{*}$ adduct include dissociation back to reactants, elimination via 4 -member ring or 3 -menber ring transition states, isomerization, and bond fission to dissociation products.

Table 3.1 Harmonic Vibrational Frequencies and Moments of Inertia
$\left.\begin{array}{crrrrrrc}\hline \text { species } & & & \text { frequencies }\left(\mathrm{cm}^{-1}\right)\end{array} \quad \begin{array}{c}\text { moments of inertia } \\ (\mathrm{amu}-\mathrm{Bohr} \text { ) })\end{array}\right]$

The optimized geometries of six transition states at the B3LYP/6-31G(d,p) level are shown in Table A.7, and corresponding vibrational frequencies and moments of inertia are listed in Table 3.1.

The potential energy diagram for $\mathrm{CH}_{2} \mathrm{Cl}+\mathrm{OH}$ reaction system calculated at the CBS-Q level is shown in Figure 3.1.

Figure 3.1 Potential energy for $\mathrm{CH}_{2} \mathrm{Cl}+\mathrm{OH}$.

Enthalpies for transition states in Figure 3.1 are calculated by two methods. The first method is straightforward using the $\Delta H_{\mathrm{f}, 298}$ value of stable adduct plus the difference of total energies between adduct and transition state. The second method takes an average of: (i) the calculated energy difference between transition state and adduct; and (ii) the difference between transition state and products plus enthalpy of reaction $\left(\Delta H^{\circ}{ }_{r x n}\right)$. The
reaction enthalpies for six transition states in $\mathrm{CH}_{2} \mathrm{Cl}+\mathrm{OH}$ system determined by these two methods at three different levels are listed in Table 3.2. It can be seen that the reaction enthalpies calculated from forward reaction (Method 1) show good agreement with the average values (Method 2) for all the six reactions at the CBS-Q level. Enthalpies of formation for transition states calculated by first method at the CBS-Q level are used to calculate rate constants.

### 3.3.2 Reactions in $\mathrm{CH}_{2} \mathrm{Cl}+\mathrm{OH}$ System

3.3.2.1 Elimination. The $\mathrm{CH}_{2} \mathrm{ClOH}^{*}$ adduct can undergo molecular elimination of HCl via two different transition states TS1 and TS2. TS1 is the hydroxyl H and the Cl eliminated from $\mathrm{CH}_{2} \mathrm{ClOH}^{*}$ to form $\mathrm{HCl}+\mathrm{CH}_{2} \mathrm{O}$ with barrier of $39.50 \mathrm{kcal} \mathrm{mol}^{-1}$. The TS2 has the H and Cl atoms eliminate from chloromethyl group in $\mathrm{CH}_{2} \mathrm{ClOH}^{*}$ to form a siglet di-radical ${ }^{1} \mathrm{CHOH}$ plus HCl with barrier of $63.19 \mathrm{kcal} \mathrm{mol}^{-1}$.

Other elimination channels from the $\mathrm{CH}_{2} \mathrm{ClOH}^{*}$ adduct are: $\mathrm{H}_{2} \mathrm{O}$ elimination forming a diradical ${ }^{1}: \mathrm{CHCl}$ with barrier of $81.27 \mathrm{kcal} / \mathrm{mol} ; \mathrm{H}_{2}$ elimination forming formyl chloride CHClO with barrier of $87.77 \mathrm{kcal} \mathrm{mol}^{-1} ; \mathrm{H}_{2}$ elimination forming a diradical
${ }^{1} \mathrm{CClOH}$ with barrier of $98.92 \mathrm{kcal} \mathrm{mol}^{-1}$. These reaction paths with high barrier and tight transition states, are energetically unimportant in the atmospheric environmental chemistry.
3.3.2.2 Bond Fission. The $\mathrm{C}-\mathrm{Cl}, \mathrm{C}-\mathrm{H}$, and $\mathrm{O}-\mathrm{H}$ bond cleavage reactions from the $\mathrm{CH}_{2} \mathrm{ClOH}^{*}$ adduct will produce three radical sets: $\mathrm{C} \cdot \mathrm{H}_{2} \mathrm{OH}+\mathrm{Cl}, \mathrm{C} \cdot \mathrm{HClOH}+\mathrm{H}$, and $\mathrm{CH}_{2} \mathrm{ClO} \cdot+\mathrm{H}$, respectively. These bond fission reactions are the reverse process of the barrier-less radical-radical association. The bond dissociation energies are calculated as $81.36,94.91,104.58 \mathrm{kcal} \mathrm{mol}^{-1}$, respectively. These bond fission recctions will not occur at low and intermediate temperatures.
3.3.2.3 Isomerization. $\mathrm{CH}_{2} \mathrm{ClOH}$ can isomerize to methyl hypochlorite $\mathrm{CH}_{3} \mathrm{OCl}$ via TS6, which involves the migration of hydroxyl H atom to the C atom accompanied by migration of the Cl atom to the O atom. This is inferring a transition state structure with moving atoms on apposite side of a plane. The activation energy is calculated to be $123.57 \mathrm{kcal} / \mathrm{mol}$. It implies that $\mathrm{CH}_{3} \mathrm{OCl}$ is kinetically stable; however, the energy of $\mathrm{CH}_{3} \mathrm{OCl}$ is $42.66 \mathrm{kcal} \mathrm{mol}^{-1}$ higher than that of $\mathrm{CH}_{2} \mathrm{ClOH}$. The high barrier indicates that this reaction is not important.

### 3.3.3 Bimolecular Association of $\mathrm{CH}_{2} \mathbf{C l}+\mathbf{O H}$

The potential energy for association of $\mathrm{CH}_{2} \mathrm{Cl}$ to OH was calculated by varying the equilibrium $\mathrm{C}-\mathrm{O}$ bond length $1.3742 \AA$ to $4.3742 \AA$ with interval of $0.1 \AA$ at the B3LYP/6-31G(d,p) level. A smooth energy potential is obtained as illustrated in Figure 3.2. The DFT calculated total energies at each point are fitted by a Varshni potential energy function ${ }^{89}$ with the parameters $\beta=0.4095 \AA$ and $D_{e}=99.90 \mathrm{kcal} / \mathrm{mol}$ (without ZPE correction). The dissociation energy $D_{e}$ is predicted at the CBS-QB3 level of theory.

The Lennard-Jones parameters for $\mathrm{CH}_{2} \mathrm{ClOH} \cdots \mathrm{N}_{2}$ pair are assumed to be the same as those of the $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{Cl} \cdots \mathrm{N}_{2}$ pair, $\sigma=3.62 \AA, \varepsilon / \mathrm{k}=97.5 \mathrm{~K} .{ }^{90}$

Figure 3.2 Bond dissociation energy for $\mathrm{CH}_{2} \mathrm{ClOH} \rightarrow \mathrm{CH}_{2} \mathrm{Cl}+\mathrm{OH}$.

The calculated bimolecular reaction rate constant vs. temperature for $\mathrm{CH}_{2} \mathrm{Cl}+\mathrm{OH}$ at the atmospheric condition by VariFlex code is shown in Figure 3. The rate constant can be expressed in units of $\mathrm{cm}^{3} \mathrm{~mol}^{-1} \mathrm{~s}^{-1}$ at the temperature range of $300 \sim 3000 \mathrm{~K}$ by the equation: $k=8.44 \times 10^{12} \mathrm{~T}^{0.276} \exp (132.23 / \mathrm{T})$.

Humpfer et al. ${ }^{91}$ measured the association rate constant of $\mathrm{CH}_{3}+\mathrm{OH}$ by mass spectrometry at $\mathrm{T}=300 \sim 700 \mathrm{~K}$ and very low pressure range to be: $k=1.02 \times 10^{14} \mathrm{~cm}^{3}$ $\mathrm{mol}^{-1} \mathrm{~s}^{-1}$. Baulch et al. ${ }^{92}$ in an extensive literature review, reported this rate constant to be: $k=6.03 \times 10^{13} \mathrm{~cm}^{3} \mathrm{~mol}^{-1} \mathrm{~s}^{-1}$. Fagerstrom et al. ${ }^{93}$ measured the rate constant for $\mathrm{C}_{2} \mathrm{H}_{5}$
+OH to be: $k=7.69 \times 10^{13} \mathrm{~cm}^{3} \mathrm{~mol}^{-1} \mathrm{~s}^{-1}$ at $\mathrm{T}=200 \sim 400 \mathrm{~K}$ and $\mathrm{P}=0.247 \sim 0.987 \mathrm{~atm}$. Jungkamp et al. ${ }^{94}$ measured the association rate constant of $\mathrm{CH}_{3} \mathrm{O}+\mathrm{Cl}$ at 300 K using a discharge flow system with laser-induced fluorescence (LIF) and mass-spectrometric detection as: $k=6.02 \times 10^{13} \mathrm{~cm}^{3} \mathrm{~mol}^{-1} \mathrm{~s}^{-1}$, and Daele et al. ${ }^{95}$ measured it as: $k=1.17 \times 10^{13}$ $\mathrm{cm}^{3} \mathrm{~mol}^{-1} \mathrm{~s}^{-1}$ using the same techniques. Compared with these experimental data, our theoretically predicted rate constant for $\mathrm{CH}_{2} \mathrm{Cl}+\mathrm{OH}$ has reasonable accuracy.

Figure 3.3 Calculated association rate constant of $\mathrm{CH}_{2} \mathrm{Cl}+\mathrm{OH}$ at $\mathrm{P}=1 \mathrm{~atm}$.

### 3.3.4 Decomposition of $\mathbf{C H}_{2} \mathbf{C l O H}$

The high-pressure limit rate constants $\left(\mathrm{k}_{\infty}\right)$ for the $\mathrm{CH}_{2} \mathrm{ClOH}$ dissociation are determined by canonical transition state theory using structural parameters and vibration frequencies of the transition states in this study. The thermochemical data of stable species are taken from our previous study, ${ }^{46}$ which is cooperated with internal rotation analysis. The highpressure limit rate constants used in QRRK analysis are fitted by three parameters $A_{\infty}, \mathrm{n}$, and $E_{\mathrm{a}}$ over temperature range from 298 to 2000 K ; these values are listed in Table 3.3, and barriers are shown in Figure 3.1.

Table 3.3 Kinetic Parameters for QRRK Analysis in $\mathrm{CH}_{2} \mathrm{Cl}+\mathrm{OH}$ System

| reaction | $A\left(\mathrm{~s}^{-1} \mathrm{or} \mathrm{cm}^{3} \mathrm{~mol}^{-1} \mathrm{~s}^{-1}\right)$ | $n$ | $E_{a}\left(\mathrm{kcal} \mathrm{mol}^{-1}\right)$ |

The calculated temperature dependent rate constants for chemically activated $\mathrm{CH}_{2} \mathrm{Cl}+\mathrm{OH}$ reaction system at 1 atm from the QRRK combined with Master equation analysis are illustrated in Figure 3.4. The dominant product-channel for $\mathrm{CH}_{2} \mathrm{Cl}+\mathrm{OH}$ is the dissociation to $\mathrm{CH}_{2} \mathrm{O}+\mathrm{HCl}$ at all temperatures due to its low barrier. The next dominant product-channel is dissociation to $\mathrm{C} \cdot \mathrm{H}_{2} \mathrm{OH}+\mathrm{Cl}$ at all temperature range since it has relative higher A factor due to its reverse reaction is barrier-less radical-radical
association reaction. Figure 3.5 illustrates the calculated rate constants vs. pressure for the chemically activated reaction $\mathrm{CH}_{2} \mathrm{Cl}+\mathrm{OH}$ at 1000 K ; it shows these rate constants have no pressure dependence over $0.001 \sim 10 \mathrm{~atm}$.

Figure 3.4 Rate constants vs. T for $\mathrm{CH}_{2} \mathrm{Cl}+\mathrm{OH}$ system at $\mathrm{P}=1 \mathrm{~atm}$.

The unimolecular dissociation of stabilized $\mathrm{CH}_{2} \mathrm{ClOH}$ to products vs. temperature at 1 atm is shown in Figure 3.6, and its pressure dependent dissociation rate constants at $\mathrm{T}=1000 \mathrm{~K}$ is shown in Figure 3.7. The dominant product-channel for $\mathrm{CH}_{2} \mathrm{ClOH}$ is the dissociation to $\mathrm{CH}_{2} \mathrm{O}+\mathrm{HCl}$ at all temperatures, and this channel shows a small pressure dependence in the range of $0.001 \sim 10 \mathrm{~atm}$. The calculated rate constant for this dissociation is: $k=6.62 \times 10^{27} \mathrm{~T}^{-4.83} \exp (21801 / \mathrm{T}) \mathrm{s}^{-1}$ at 1 atm , which is well below than the upper limit inferred from the experiment results of Wallington et al. ${ }^{81}$

Figure 3.5 Pressure dependent rate constant $\mathrm{CH}_{2} \mathrm{Cl}+\mathrm{OH}$ at $\mathrm{T}=1000 \mathrm{~K}$.

Figure 3.6 Rate constants vs. T for dissociation of $\mathrm{CH}_{2} \mathrm{ClOH}$ at $\mathrm{P}=1 \mathrm{~atm}$.

Wallington et al. reported that the first-order loss rates of $(3.4 \pm 0.2) \times 10^{-3} \mathrm{~s}^{-1}$ for $\mathrm{CH}_{2} \mathrm{ClOH},(5.5 \pm 0.3) \times 10^{-3}$ for $\mathrm{CHCl}_{2} \mathrm{OH}$, and $(9.9 \pm 0.2) \times 10^{-3}$ for $\mathrm{CCl}_{3} \mathrm{OH}$ in a chamber, and the decays of $\mathrm{CH}_{2} \mathrm{ClOH}$ and $\mathrm{CHCl}_{2} \mathrm{OH}$ rate is $(1.6 \pm 0.1) \times 10^{-3} \mathrm{~s}^{-1}$ and $(9.0$ $\pm 0.8) \times 10^{-3} \mathrm{~s}^{-1}$ at another different chamber. They ascribed such differences to heterogeneous decomposition, which is sensitive to the nature and history of the surface of chamber. Their experiments were performed at a total pressure of 700 Torr at $295 \pm 2$ K, and they concluded that the three chloromethanols have lifetimes of at least 100 seconds (and probably much longer) with respect to homogeneous decomposition in the gas phase, but can decompose rapidly on surface. We suspect they will also decompose rapidly in heterolysis reaction environments.

Figure 3.7 Rate constant vs. P for dissociation of $\mathrm{CH}_{2} \mathrm{ClOH}$ at $\mathrm{T}=1000 \mathrm{~K}$.

In this study, the half-life is calculated as 17.6 seconds for the homogeneous decomposition of chloromethanol at 600 K , but its half-life is much longer at room temperature. Our computational results and experimental data suggest that the reported stability and slow homogeneous decay of chloromethanol under atmospheric conditions, where heterogeneous and homogeneous decompositions presented are not inconsistent. However, the decomposition of $\mathrm{CH}_{2} \mathrm{ClOH}$ will be rapid in combustion environment or in a thermal heterogeneous / catalysis processes.

This dissociation of activated chloromethanol and other chlorinated methanols, may be a significant mechanism to convert Cl into HCl in stratosphere; particularly for trichloro-methyl radical, which has a little reaction with $\mathrm{O}_{2}$.

### 3.4 Summary

Potential energy surfaces for $\mathrm{CH}_{2} \mathrm{Cl}+\mathrm{OH}$ reaction system are calculated based on DFT B3LYP/6-31G(d,p), ab initio QCISD(T)/6-31G(d,p) and CBS-Q levels of theory. The rate constants for bimolecular association of OH with $\mathrm{CH}_{2} \mathrm{Cl}$ radical are calculated to be: $k=1.48 \times 10^{13} \mathrm{~T}^{0.292} \exp (61.46 / \mathrm{T}) \mathrm{cm}^{3} \mathrm{~mol}^{-1} \mathrm{~s}^{-1}$ based on variational transition state theory. The high-pressure limit rate constants $\left(\mathrm{k}_{\infty}\right)$ for reactions with saddle point transition states are determined by canonical transition state theory. Branching ratios of the energized $\mathrm{CH}_{2} \mathrm{ClOH}$ adduct to stabilization and product channels are calculated using multi-frequency Quantum Rice-Rampsperger-Kassel (QRRK) theory for $k(\mathrm{E})$ combined with master equation analysis for pressure fall-off. Kinetic parameters for product channels of $\mathrm{CH}_{2} \mathrm{Cl}+\mathrm{OH}$ system are presented versus temperature and pressure. The activated $\mathrm{CH}_{2} \mathrm{ClOH}^{*}$ adduct dissociation to $\mathrm{CH}_{2} \mathrm{O}$ plus HCl is the most important
channel below 1500 K at pressure range of $0.001 \sim 10 \mathrm{~atm}$. The calculated rate constants are useful for predicting reaction paths in applications of combustion and atmospheric modeling regimes, where experimental data are not available.

## CHAPTER 4

## THERMOCHEMICAL AND KINETIC ANALYSIS ON THE REACTION OF NEOPENTYL RADICAL WITH MOLECULAR OXYGEN

### 4.1 Overview

Thermochemical properties for reactants, intermediates, products and transition states in the neopentyl radical $+\mathrm{O}_{2}$ reaction system are analyzed with $a b$ initio and density functional calculations to evaluate reaction paths and kinetics for neopentyl oxidation. Enthalpies of formation ( $\Delta H_{f}^{o} 298$ ) are determined using isodesmic reaction analysis at the CBS-Q composite and density functional levels. The entropies $\left(S^{\circ}{ }_{298}\right)$ and heat capacities $C_{p}(T)$ 's $(0 \leq T / \mathrm{K} \leq 1500)$ from vibrational, translational, and external rotational contributions are calculated using statistical mechanics based on the vibrational frequencies and structures obtained from the density functional study. Potential barriers for the internal rotations are calculated at the B3LYP/6-31G(d,p) level, and hindered rotational contributions to $S^{0}{ }_{298}$ and $C_{p}(T)$ 's are calculated by using direct integration over energy levels of the internal rotational potentials. The kinetic analysis on reactions of neopentyl with $\mathrm{O}_{2}$ is preformed at the CBS-Q calculation level. The reaction forms a chemically activated neopentyl peroxy adduct with energy of $38.13 \mathrm{kcal} \mathrm{mol}^{-1}$. The energized adduct can be stabilized, dissociate back to reactants or isomerize to hydroperoxy-neopentyl radical. The isomer can dissociate to 3,3-dimethyloxetane +OH , to isobutene $+\mathrm{CH}_{2} \mathrm{O}+\mathrm{OH}$, to methyl + 2-methyl-2-propenyl-hydroperoxide, isomerize back to neopentyl peroxy radical, or further react with $\mathrm{O}_{2}$. The $\Delta H_{f}^{o}$ 298 values for the neopentyl, neopentyl peroxy and hydroperoxy-neopentyl radicals are calculated as 10.52 , -27.61 , and $-9.43 \mathrm{kcal} \mathrm{mol}^{-1}$ at the CBS-Q level. Rate constants to products and
stabilized adducts (isomers) of the chemically activated neopentylperoxy are calculated as functions of pressure and temperature using quantum Rice-Ramsperger-Kassel (QRRK) analysis for $k(E)$ and a master equation analysis for pressure fall-off. An elementary reaction mechanism is constructed to model experimental OH formation profile; it shows that the further reactions of the hydroperoxy-neopentyl radical with $\mathrm{O}_{2}$ have contributions to the OH profile. Kinetic parameters for intermediate and product formation channels of the neopentyl $+\mathrm{O}_{2}$ system are presented versus temperature and pressure.

### 4.2 Background

#### Abstract

ion reactions that form alkyl radicals in atmospheric and combustion reaction systems are well characterized, relative to subsequent association reactions of the radical with $\mathrm{O}_{2}$, which form a chemically activated peroxy radical that can undergo a number of isomerization and dissociation reactions before becoming stabilized. These $\mathrm{R} \cdot$ plus $\mathrm{O}_{2}$ reactions are relatively complex; they involve formation of a peroxy radical, which contains $30 \sim 40 \mathrm{kcal} \mathrm{mol}^{-1}$ of excess internal energy, this can either be lost via collision processes or used for further reaction before stabilization occurs. ${ }^{98}$ These reactions are important rate controlling processes in the low and intermediate temperature chemistry of hydrocarbon oxidation, especially the chemistry which occurs prior to ignition in internal combustion engines and in cool flames. The reactions of the alkyl peroxy radical intermediate are, in addition, considered essential to predict negative temperature coefficient (NTC) behavior. ${ }^{99}$ Many combustion reaction mechanisms consider the overall reaction of alkyl radicals with $\mathrm{O}_{2}$ to form conjugate alkenes plus $\mathrm{HO}_{2}$ to be

dominant processes over the 500 to 900 K temperature ranges, but the details of the pathway(s) are not treated consistently and in some cases the path is not correct. Some authors ${ }^{100,101}$ ascribe this reaction to the abstraction of a H atom by $\mathrm{O}_{2}$, while others ${ }^{26,102,103}$ consider it a direct molecular elimination, still others consider it as an isomerization (hydrogen atom transfer) to a hydroperoxy-alkyl isomer that undergoes further reaction ( $\beta$-scission) to products.

Two features of neopentyl radical facilitate a simpler interpretation of experimental results relative to most alkyl radical oxidation systems: (a) All the $\mathrm{C}-\mathrm{H}$ bonds in the methyl groups are identical, so only one alkyl radical is involved. (b) The carbon radical site is connected to a quartenary carbon, and the formation of $\mathrm{C}_{5}$ conjugate alkene $+\mathrm{HO}_{2}$ is structurally impossible by the above routes. This property of the neopentyl structure eliminates the concerted $\mathrm{HO}_{2}$ elimination path from the peroxy adducts, only reactions involving stabilization, dissociation by reverse reaction, isomerization and isomer decomposition are dominant here.

There are several experimental and modeling studies on neopentyl radical oxidation. ${ }^{104-114}$ Hughes et al ${ }^{104,105}$ measured the time dependence of OH radical from photolysis of neopentyl iodide in helium bath with varied concentrations of $\mathrm{O}_{2}$ at temperatures from 660 to 750 K . An exact analytical solution was postulated incorporating neopentyl decomposition, reversible peroxy formation, and irreversible hydrogen atom transfer isomerization based on the assumption of fast subsequent decomposition via various channels to OH , which given the low species concentration present would be lost primarily by diffusion out of the photolysis zone. OH radical concentration profiles versus time were obtained by laser-induced fluorescence (LIF) and
fitted to a biexponential function, which is combination with the proposed analytical solution allowed rate coefficients for the isomerization process to be extracted and hence, Arrhenius parameters to be calculated as an A factor of $1.58 \times 10^{12} \mathrm{~s}^{-1}$ and $\mathrm{E}_{\mathrm{a}}$ of 29 kcal $\mathrm{mol}^{-1}$.

The research group of Baldwin and Walker ${ }^{106}$ studied the reactions of neopentyl radical in an oxidizing environment using a flow reactor with reaction times ranging up to tens of seconds, with product analysis by gas chromatography. They reported the stable products 3,3-dimethyloxetane, acetone, isobutene, and formaldehyde as a function of oxygen concentration at temperatures from 653 to 793 K . They suggested a mechanism for quantitative interpretation of product yields using steady state and equilibrium relationships, and hence determined Arrhenius parameters for elementary reactions in their mechanism.

Bayes research group ${ }^{107,108}$ studied the rate constants of neopentyl radical with $\mathrm{O}_{2}$ at 266 to 374 K and low pressure of 3 to 3.5 torr. They monitored the pseudo-first-order decay of the neopentyl radicals as a function of partial pressure of $\mathrm{O}_{2}$ using mass spectrometric detection. Their experimental results show negative temperature dependence for the rate constant of neopentyl radical with $\mathrm{O}_{2}$. They used an adiabatic channel model calculation to interpret their results with no fall-off analysis and reported the rate constant of this reaction as $k=\left\{1.3 \times 10^{12} \mathrm{~cm}^{3} \mathrm{~mol}^{-1} \mathrm{~s}^{-1}\right\}(\mathrm{T} / 300 \mathrm{~K})^{-(2.1 \pm 0.4)}$.

Dagaut et al. ${ }^{111}$ studied the oxidation of neopentane in a jet-stirred reactor at pressures of 1,5 , and 10 atm , and temperatures of 800 to 1230 K using probe-sampling of stable species and off-line gas chromatograph analyses. They provided an elementary mechanism to model the concentration profiles of the reactants, stable intermediates, and
products such as $\mathrm{CO}, \mathrm{CO}_{2}$, and hydrocarbons. Their modeling focused on high temperature experiments and their studies were not sensitive to the reactions of peroxy radicals because the $\beta$-scission of neopentyl radical to isobutene plus methyl radical dominated at these temperatures.

Curran et al. ${ }^{114}$ published a detailed kinetic model on the oxidation of neopentane and compared the experimental results at 500 torr and 753 K by Baker et al, ${ }^{109,110}$ and later they modified their mechanism in conjunction with new data from high pressure flow reactor experiments. ${ }^{113}$ They estimated thermochemical and kinetic parameters using THERM ${ }^{115}$ and other techniques to model stable end-product profiles without transition state or fall-off analysis.

Taatjes et al. ${ }^{103}$ recently measured the time-resolved production of OH and $\mathrm{HO}_{2}$ in pulsed-photolytic Cl-initiated oxidation of neopentane between 573 and 750 K . They observed that their OH measurements are especially sensitive to the direct pathways from $\mathrm{R}+\mathrm{O}_{2}$ to QOOH and to $\mathrm{OH}+3,3$-dimethyloxetane. They also proposed a kinetic model based on comparison with their previous time-dependent master equation calculation of analogous processes in the reaction of n-propyl with $\mathrm{O}_{2}$ for modeling OH and $\mathrm{HO}_{2}$ concentration vs. time profiles at different temperatures.

Thermochemical and kinetic parameters in our theoretical model are based on $a b$ initio and density functional calculations, and the reaction mechanism for the neopentyl radical $+\mathrm{O}_{2}$ system is outlined in the following scheme:

Treatment of the energized complex reactions in our mechanism includes analysis of the decomposition back to reactants, intramolecular transfer of hydrogen atoms to form a hydroperoxy alkyl radical, which can dissociate to products before stabilization. Further isomerizations, dissociations of the stabilized neopentyl peroxy radical and the hydroperoxide alkyl isomer are also included along with a second $\mathrm{O}_{2}$ addition to the hydroperoxy-neopentyl radical. Several other important reaction paths, as illustrated above, are also included in the elementary reaction mechanism.

Thermochemical properties of reactants, intermediates, products and transition states for the elementary reactions are calculated by $a b$ initio and density functional calculations with analysis of internal rotation barriers at the DFT level. High-pressure limit rate constants are calculated by canonical transition state theory or evaluated from literature. Quantum RRK theory ${ }^{17,116-118}$ is used for analysis of $k(E)$ and a master equation ${ }^{26}$ analysis for fall-off in a kinetic analysis on the chemical activation and
unimolecular dissociation reaction systems. The rate constants are incorporated into a detailed elementary reaction mechanism and are shown to tmodel the experimental OH profile of Hughes et al ${ }^{104}$ well. The mechanism also models the experimental $\mathrm{HO}_{2}$ profile of Taatjes et al well. ${ }^{103}$

### 4.3 Calculation Method

### 4.3.1 Computational Details

The geometries of reactants, important intermediates, transition states and products in neopentyl $+\mathrm{O}_{2}$ reaction system are pre-optimized using PM3 MOPAC ${ }^{84}$ calculations, followed by optimizations and frequency calculations at the B3LYP/6-31G(d,p) level using the Gaussian 98 program. ${ }^{32}$ The optimized structure parameters are then used to obtain total electronic energies at the B3LYP/6-311++G(3df,2p) and CBS-Q single point levels of calculation. The potential energies for the neopentyl $+\mathrm{O}_{2}$ system are calculated at the CBS-Q level. For the secondary reaction system - addition of an $\mathrm{O}_{2}$ to the hydroperoxy neopentyl radical, the potential energies are calculated at the B3LYP/6$311++G(3 \mathrm{df}, 2 \mathrm{p})$ level due to the relatively large molecule size. For iodine-containing species, the effective core-potential basis sets and modified diffuse $s p$ functions and d polarization function are employed. ${ }^{119,120}$ Rotational barriers for the internal rotational potentials are calculated at the $\mathrm{B} 3 \mathrm{LYP} / 6-31 \mathrm{G}(\mathrm{d}, \mathrm{p})$ level.

### 4.3.2 Thermochemical Properties

Contributions from vibrational, translational, external rotational, and electronic to entropies and heat capacities are calculated by statistical mechanics based on the vibrational frequencies and moments of inertia from the DFT optimized structures. The
torsion frequencies are identified by viewing bond motions in the GaussView98 program, ${ }^{121}$ and these torsion frequencies are omitted in calculation of $S^{\circ}{ }_{298}$ and $C_{p}(T)$ 's, and their contributions are replaced with values from analysis of the internal rotations. Contributions from hindered rotors to $S_{298}^{0}$ and $C_{p}(T)$ 's are determined by solving the Schrödinger equation with free rotor wave functions, and the partition coefficients are treated by direct integration over energy levels of the intramolecular rotational potential curves which are represented by a truncated Fourier series expansion. The $\Delta H_{\mathrm{f}}{ }_{298}{ }^{0}$ values for reactants, intermediate and products are calculated using total energies from ab initio and DFT calculations and isodesmic reactions with group balance when possible. Transition state (TS) geometries are identified by the existence of only one imaginary frequency in the normal mode coordinate analysis, evaluation of the TS geometry, and the reaction coordinate's vibrational motion. The $\Delta H_{\mathrm{f}}{ }^{\circ} 298$ values of transition state structures are calculated by the $\Delta H_{\mathrm{f}}{ }^{\circ} 298$ of the stable radical adducts from working isodesmic reaction analysis, plus the difference of total energies between the radical adducts and the transition states.

### 4.3.3 Kinetic Analysis

Unimolecular dissociation and isomerization reactions of the chemically activated and stabilized adducts resulting from addition or combination reactions are analyzed by first constructing potential energy diagrams for the reaction system. DFT and ab initio calculations are used to calculate transition state structures and activation energy for isomerization, $\beta$ - scission, and dissociation reactions. The enthalpies and entropies are treated with conventional transition state theory to calculate Arrhenius pre-exponential factors and energies of activation that result in high-pressure limit rate constants $\left(k_{\infty}\right)$ as
functions of temperature. Nonlinear Arrhenius effects resulting from changes in the thermochemical properties of the respective transition state relative to its adduct with temperature are incorporated using two parameter Arrhenius pre-exponential factor $(A, n)$ in $A T^{n}$. High-pressure limit pre-exponential factors for association reactions are obtained from the literature. Equilibrium constants $K_{e q}(T)$ are calculated from thermodynamic properties of reactants and products as a function of temperature. Reverse rate constants are calculated from the principle of microscopic reversibility. Branching ratios of the energized adduct to stabilization and product channels are calculated using multifrequency Quantum Rice-Rampsperger-Kassel (QRRK) analysis for $k(E)^{66,115}$ with the steady-state assumption on the energized adduct(s) in combination with a master equation analysis ${ }^{26,122}$ for pressure fall-off.

The QRRK calculation evaluates energy dependent rate constants, $k(\mathrm{E})$, of the energized adduct to each channel for the bimolecular chemical activation reaction and includes equilibrium in isomerization reactions. The QRRK analysis described by Chang et al. ${ }^{17}$ and Sheng et al. ${ }^{26}$ is shown to yield reasonable results and provides a framework by which the effects of temperature and pressure can be evaluated in these complex reaction systems. The QRRK code utilizes a reduced set of three vibration frequencies and their associated degeneracies which accurately reproduce the adduct heat capacity and include one external rotation in calculation of accurate ratios of density of states to partition coefficient, $\rho(\mathrm{E}) / Q .{ }^{18}$

Evaluations on the steady state QRRK chemical activation analysis we utilize indicate that it is valid at reaction times on the order of nanoseconds; analysis for longer
times of reaction may require use of the CHEMKIN analysis in order to include reactions of the stabilized adducts depending on temperature, pressure and rate constants.

A 0.5 kcal energy grain used to obtain rate constants as a function of temperature and pressure for chemical activation and dissociation reactions. $(\Delta E)^{\circ}$ down of 570 cal $\mathrm{mol}^{-1}$ is used in the master equation analysis with helium as the third body. LennardJones parameters, $\sigma$ (Angstroms) and $\varepsilon / \kappa$ (Kelvins), are obtained from tabulations ${ }^{90}$ and from an estimation method based on molar volumes and compressibility.

### 4.4 Results and Discussion

### 4.4.1 Geometries

The geometry optimizations for the reactants, transition states, adducts, and products in the neopentyl oxidation system are performed at the B3LYP/6-31G(d,p) level, and the effective core-potential basis sets and modified diffuse $s p$ functions and $d$ polarization function ${ }^{120}$ are used for iodine-containing species. The optimized structural parameters for 33 species including transition state structures are listed in Appendix Table B.1. The corresponding unscaled vibrational frequencies and moments of inertia are listed in Table B.2. The notations of several important species in this system are defined as: $\mathrm{C}_{3} \mathrm{CC} \cdot$ (neopentyl radical), $\mathrm{C}_{3} \mathrm{CCOO} \cdot$ (neopentyl peroxy radical), $\mathrm{C}_{3} \cdot \mathrm{CCOOH}$ (hydroperoxyneopentyl radical), $\mathrm{C}_{2} \mathrm{CYCCOC}$ (3,3-dimethyloxetane), $\mathrm{C}_{2} \mathrm{C}(\mathrm{OOH}) \mathrm{COO} \cdot$ (hydroperoxyneopentylperoxy radical), $\quad \mathrm{C}_{2} \cdot \mathrm{C}(\mathrm{COOH})_{2} \quad$ (dihydroperoxide-neopentyl radical), $\mathrm{C}(\mathrm{COOH}) \mathrm{CYCCOC}$ (3-methyl,3-hydroperoxideoxetane), $\mathrm{C}=\mathrm{C}(\mathrm{C}) \mathrm{COOH}$ (isobutenyl hydroperoxide), $\mathrm{C}_{2} \mathrm{C}(\mathrm{COOH}) \mathrm{CHO}$ (2-methyl isopropanal-2-methylhydroperoxide), $\mathrm{C}_{2} \mathrm{C}(\mathrm{CHO}) \mathrm{CH}_{2} \mathrm{O}$ • (2-methyl isopropanal-2-methyoxy radical), and $\mathrm{C}_{3} \mathrm{CCI}$
(neopentyliodide). The transition states of important reactions in this oxidation system are identified as follows:

## Alkyl peroxy radical isomerization

$\mathrm{C}_{3} \mathrm{CCOO} \cdot \rightarrow \mathrm{TS1} \rightarrow \mathrm{C}_{3} \cdot \mathrm{CCOOH}$
$\mathrm{C}_{2} \mathrm{C}(\mathrm{OOH}) \mathrm{COO} \bullet \rightarrow \mathrm{TS} 7 \rightarrow \mathrm{C}_{2} \bullet \mathrm{C}(\mathrm{COOH})_{2}$
This reaction represents intramolecular, endothermic, transfer of a H atom from a primary methyl carbon atom to the peroxy oxygen radical site via a 6-member ring transition state including the H atom. The cleaving $\mathrm{C}-\mathrm{H}$ bond stretches to $1.40 \AA$ from $1.09 \AA$, and the forming $\mathrm{O}-\mathrm{H}$ bond length is $1.14 \AA$, which is longer than that of normal O-H bond, $0.978 \AA$.

## Epoxide formation

$\mathrm{C}_{3} \cdot \mathrm{CCOOH} \rightarrow \mathrm{TS} 3 \rightarrow \mathrm{C}_{2} \mathrm{CYCCOC}+\mathrm{OH}$
$\mathrm{C}_{2} \cdot \mathrm{C}(\mathrm{COOH})_{2} \rightarrow \mathrm{TS} 9 \rightarrow \mathrm{C}(\mathrm{COOH}) \mathrm{CYCCOC}+\mathrm{OH}$
In this reaction type, the carbon radical in the $-\mathrm{CH}_{2} \bullet$ group attacks the peroxy oxygen to form 4-member ring transition state; while the weak $\mathrm{RO}-\mathrm{OH}$ bond is breaking. The cleaving $\mathrm{O}-\mathrm{O}$ bond length is $1.68 \AA$ and the forming $\mathrm{C}-\mathrm{O}$ bond length is
$1.99 \AA$. This reaction is responsible for a major fraction of the OH formation.
$\beta$-scission of alkyl radicals
$\mathrm{C}_{3} \mathrm{CC} \cdot \rightarrow \mathrm{TS} 0 \rightarrow \mathrm{C}_{2} \mathrm{C}=\mathrm{C}+\mathrm{CH}_{3}$
$\mathrm{C}_{3} \cdot \mathrm{CCOOH} \rightarrow \mathrm{TS} 4 \rightarrow \mathrm{C}_{2} \mathrm{C}=\mathrm{C}+\mathrm{CH}_{2} \mathrm{O}+\mathrm{OH}$
$\mathrm{C}_{3} \cdot \mathrm{CCOOH} \rightarrow \mathrm{TS} 5 \rightarrow \mathrm{C}=\mathrm{C}(\mathrm{C}) \mathrm{COOH}+\mathrm{CH}_{3}$
$\mathrm{C}_{2} \cdot \mathrm{C}(\mathrm{COOH})_{2} \rightarrow \mathrm{TS} 10 \rightarrow \mathrm{C}=\mathrm{C}(\mathrm{C}) \mathrm{COOH}+\mathrm{CH}_{2} \mathrm{O}+\mathrm{OH}$

These reactions involve cleavage of an alkyl or oxy-alkyl group moving perpendicular from a near planar isobutenyl structure with simultaneous formation of a $\pi$ bond (olefin here) on the same carbon. For methyl group dissociation, the $\mathrm{C}-\mathrm{C}$ bond length stretches from $1.58 \AA$ to $2.31 \AA$, and the forming $\mathrm{C}=\mathrm{C}$ bond length is $1.37 \AA$ in the TS0 and TS5 structures.

At temperatures above $1200^{\circ} \mathrm{C}$, unimolecular dissociation of the neopentyl radical via TS0, is the primary reaction relative to reaction with $\mathrm{O}_{2}$.

For the $\mathrm{CH}_{2} \mathrm{O}+\mathrm{OH}$ elimination from $\mathrm{C}_{3} \cdot \mathrm{CCOOH}$ in TS 4 , the $\mathrm{C}-\mathrm{O}$ bond length in the leaving group is decreased slightly from 1.425 to $1.366 \AA$, and $\mathrm{O}-\mathrm{O}$ bond length is slightly increased in length from 1.457 to $1.470 \AA$.

In the structure of TS10, the $\mathrm{C}-\mathrm{O}$ bond length ( $1.31 \AA$ ) is shorter than that of TS4 and the $\mathrm{O}-\mathrm{O}$ bond length $(1.78 \AA)$ is longer than that of TS4 due to interaction of the hydroperoxy H and O atoms between the two -COOH groups (see Table B .1 ).

## OH elimination from alkyl peroxy group

$\mathrm{C}_{3} \mathrm{CCOO} \rightarrow \mathrm{TS} 2 \rightarrow \mathrm{C}_{3} \mathrm{CCHO}+\mathrm{OH}$
$\mathrm{C}_{2} \mathrm{C}(\mathrm{OOH}) \mathrm{COO} \rightarrow \mathrm{TS} 8 \mathrm{~A} \rightarrow \mathrm{C}_{2} \mathrm{C}(\mathrm{COOH}) \mathrm{CHO}+\mathrm{OH}$
In this reaction group, the peroxy oxygen radical attacks the H atom in the nearest carbon via a 4 -member ring transition state. The reaction path passes through a transient intermediate $\mathrm{R}-\mathrm{C} \cdot \mathrm{OOH}$, where the carbon radical forms a $\pi$ (carbonyl) bond with the oxygen (gaining ca. $80 \mathrm{kcal} \mathrm{mol}^{-1}$ ) and cleaves the weak $\mathrm{O}-\mathrm{OH}$ bond (requiring only ca. $45 \mathrm{kcal} \mathrm{mol}^{-1}$ ). The $\mathrm{C}-\mathrm{O}$ (forming), $\mathrm{O}-\mathrm{O}$ (cleaving), and $\mathrm{O}-\mathrm{H}$ bond lengths are 1.39 , 1.50 , and 1.27 A , respectively. The changes in these bond lengths between reactant and

TS suggest that the transition state reacts through the $\mathrm{R}-\mathrm{C} \cdot \mathrm{OOH}$ structure to the intermediate $\mathrm{R}-\mathrm{CH}(=\mathrm{O})+\mathrm{OH}$.

### 4.4.2 Thermochemical Properties

4.4.2.1 Enthalpies of Formation. The enthalpies of formation for reactants, intermediate adducts and products in the neopentyl oxidation system are calculated by isodesmic reactions analysis or taken from available literature.

Table 4.1 lists the calculated reaction enthalpies and $\Delta H_{f}^{o} 298$ values for the species in the $\mathrm{C}_{3} \mathrm{CC} \cdot+\mathrm{O}_{2}$ system at three calculation levels. The calculated $\Delta H_{f}^{o}{ }_{298}$ values from
the DFT calculations show good agreement with the higher level ab initio calculations, indicating the errors in the computations for different molecules are canceled to a significant extent, ca. $\pm 2 \mathrm{kcal} \mathrm{mol}^{-1}$, by the working reactions. The agreement between the calculation levels and with the literature data suggests reasonable accuracy for the absolute enthalpy values. The average $\Delta H_{f}^{o} 298$ values from the higher level CBS-Q calculations are selected to construct our kinetic model.

Enthalpies for transition states are calculated by use of two methods. The first method is straightforward using the $\Delta H_{\mathrm{f}}{ }^{\circ} 298$ values of the stable radical adducts from the working reaction analysis, plus the difference of total energies between the radical adducts and the transition state. The second method takes an average of: (i) the calculated energy difference between the TST structure and the reactant; and (ii) the difference between TST and the products plus enthalpy of reaction $\left(\Delta H_{r x n}^{\circ}\right)$. The $\Delta H_{r x n}{ }^{\circ}$ values are calculated by the $\Delta H_{\mathrm{f}}{ }^{\circ}{ }_{298}$ values of the reactant and product, which are determined on an absolute basis by the working reaction analysis. Enthalpies of formation for six transition states in the $\mathrm{C}_{3} \mathrm{CC} \bullet+\mathrm{O}_{2}$ system determined by these two methods at the three different levels are listed in Table 4.2. It can be seen that the reaction enthalpies calculated from forward reaction (Method 1) show good agreement with the average values (Method 2) for all the six reactions at the CBS-Q level. The reaction enthalpies from DFT calculations only show good agreement with the values from CBS-Q level for the reactions with tight transition states (ring formation). Enthalpies of formation for transition states calculated from the first method at the CBS-Q level are used for the kinetic model. The $\Delta H_{f}^{o} 298$ of neopentyl radical is calculated as $10.52 \mathrm{kcal} \mathrm{mol}^{-1}$ at the CBS-Q level, which gives the $\mathrm{C}_{3} \mathrm{CC}-\mathrm{H}$ bond dissociation energy of $102.76 \mathrm{kcal} \mathrm{mol}^{-1}$
based on the published $\Delta H_{f}^{o} 298$ value for neopentane $\left(-40.14 \pm 0.15 \mathrm{kcal} \mathrm{mol}^{-1}\right) .{ }^{123}$ The above enthalpy value shows good agreement with the value, $10.36 \mathrm{kcal} \mathrm{mol}^{-1}$, reported recently by Sumathi el al. at the CBS-Q calculation level. ${ }^{124}$ Holmes el al. ${ }^{125}$ measured the heats of formation of alkyl radicals by monoenergetic electron impact, and they reported that their values agree with results from equivalent measurements using ESR spectroscopy. They reported $\Delta H_{f}^{o} 298$ of neopentyl radical as $10.1 \mathrm{kcal} \mathrm{mol}^{-1}$.

${ }^{\text {a }}$ Units in kcal mol ${ }^{-1}$. ${ }^{\mathrm{b}}$ The reaction enthalpies are calculated from forward reaction.
${ }^{\mathrm{c}}$ The reaction enthalpies are calculated from the average enthalpy values of the forward, reverse, and $\Delta H_{r x n}^{0} . \mathrm{E}_{\mathrm{a}}$,average $=1 / 2\left(\mathrm{E}_{\mathrm{a}}\right.$, forward $+\mathrm{E}_{\mathrm{a}}$, reverse $\left.+\Delta H_{\mathrm{rxn}}^{0}\right)$.

The $\Delta H_{f}^{o} 298$ of neopentyl peroxy is calculated as $-27.61 \mathrm{kcal} \mathrm{mol}^{-1}$ at the CBS-Q level; Curran et al. ${ }^{113}$ estimated it as $-26.80 \mathrm{kcal} \mathrm{mol}^{-1}$ by group additivity using THERM ${ }^{115}$. The reaction enthalpy of alkyl radicals $+\mathrm{O}_{2}$ are reported by Knyazev ${ }^{126}$ as $32.74,35.47,37.14,36.52 \mathrm{kcal} \mathrm{mol}^{-1}$ for $\mathrm{CH}_{3}, \mathrm{C}_{2} \mathrm{H}_{5}, i-\mathrm{C}_{3} \mathrm{H}_{7}, t-\mathrm{C}_{4} \mathrm{H}_{9}$, respectively; which are obtained from the third-law treatment of the temperature dependencies of the equilibrium constants $K_{p}(T)$. Clifford et al. ${ }^{127}$ reviewed the thermochemistry of alkyl peroxy radicals, and gives the reaction enthalpy of tert-butyl $+\mathrm{O}_{2}$ as $-37 \pm 2 \mathrm{kcal} \mathrm{mol}^{-1}$. The well depth for $\mathrm{C}_{3} \mathrm{CC} \cdot+\mathrm{O}_{2}$ is calculated to be $38.13 \mathrm{kcal} \mathrm{mol}^{-1}$ in this work

The $\Delta H_{\mathrm{f}}{ }^{\circ} 298$ values of hydrocarbons, substituted hydrocarbons, and corresponding radicals have been investigated in our previous studies, which show that the CBS-Q enthalpy values based on B3LYP/6-31G(d,p) optimized geometries are in agreement with accepted literature values. The CBS-Q enthalpies are more consistent than those from $\mathrm{QCISD}(\mathrm{T}) / 6-31 \mathrm{G}(\mathrm{d}, \mathrm{p})$ single point calculations when the values for one species are compared through a series of different working reactions. A comparison of $\Delta H_{\mathrm{f}}{ }^{\circ} 298$ values from CBS-Q calculations with experimental data or accepted literature data on several oxygenated hydrocarbons is listed in Table 4.3.

4.4.2.2 Internal Rotation Analysis. The calculated internal rotational potentials on the $\mathrm{C}-\mathrm{C}$ bonds of neopentyl peroxy radical and hydroperoxide neopentyl radical are shown in Figure 4.1, where the normal three-fold rotational barrier for rotation on the $\mathrm{CH}_{3}-\mathrm{C}$ bonds is illustrated. The barriers for methyl rotors are near 3.3, while the $\mathrm{C}_{3} \mathrm{C}-$ $\mathrm{COO} \bullet$ barriers are near $5 \mathrm{kcal} \mathrm{mol}^{-1}$. Figure 4.2 show the rotational potentials on the $\mathrm{C}-$ $\mathrm{OOH}, \mathrm{C}-\mathrm{OO} \cdot$ and $\mathrm{CO}-\mathrm{OH}$ bonds for the above two species, which have relatively high barriers, 4 to $7.5 \mathrm{kcal} \mathrm{mol}^{-1}$. The 6 and $7 \mathrm{kcal} \mathrm{mol}^{-1}$ barrier heights are typical of published data on these $\mathrm{CO}-\mathrm{OH}$ and $\mathrm{C}-\mathrm{OOH}$ bonds. ${ }^{77,135}$

${ }^{\mathrm{a}}$ Thermodynamic properties are referred to a standard state of an ideal gas of pure enantiometer at 1 atm . ${ }^{\mathrm{b}}$ Units in $\mathrm{kcal} \mathrm{mol}^{-1}$. ${ }^{\mathrm{c}}$ Units in cal $\mathrm{mol}^{-1} \mathrm{~K}^{-1}$. ${ }^{\mathrm{d}}$ Based on the parent and bond energy calculation.

The torsional potential on the $\mathrm{CH}_{2} \bullet-\mathrm{C}\left(\mathrm{C}_{2}\right) \mathrm{COOH}$ bond in Figure 4.3 shows a very low, six fold barrier, where only two wells have depth over $0.3 \mathrm{kcal} \mathrm{mol}^{-1}$. This $\mathrm{CH}_{2} \cdot-\mathrm{C}\left(\mathrm{C}_{2}\right) \mathrm{COOH}$ rotor is nearly a free rotor. Figure 4.3 shows both UB3LYP/6$31 \mathrm{G}(\mathrm{d}, \mathrm{p})$ and UMP2/6-31G(d,p) calculations, where the barriers are low and similar in
foldness, but the energies are somewhat different. The potential curve from the UB3LYP/6-31G(d,p) level is chosen to calculate the contribution from $\mathrm{CH}_{2} \bullet$ $\mathrm{C}\left(\mathrm{C}_{2}\right) \mathrm{COOH}$ internal rotor to $S^{0}{ }_{298}$ and $C_{p}(T)$ 's for consistency. Table 4.4 illustrates the values from vibrational, translational, external rotational contributions and also each hindered internal rotational contribution to $S_{298}^{\circ}$ and $C_{p}(T)$ 's for $\mathrm{C}_{3} \mathrm{CCOO}$ • and $\mathrm{C}_{3} \cdot \mathrm{CCOOH}$. Table 4.5 lists the thermochemical properties of important reactants, transition states, adducts, and products.

### 4.4.3 Chemical Activation Reaction Analysis

4.4.3.1 $\mathbf{C}_{3} \mathbf{C C} \cdot+\mathrm{O}_{2}$. A potential energy diagram for the $\mathrm{C}_{3} \mathrm{CC} \bullet+\mathrm{O}_{2}$ reaction system calculated at the CBS-Q level is shown in Figure 4.4. Neopentyl radical $\left(\Delta H_{\mathrm{f}}{ }^{\circ}{ }_{298}=10.52\right.$ $\mathrm{kcal} \mathrm{mol}{ }^{-1}$ ) reacts with $\mathrm{O}_{2}$ to form a $\mathrm{C}_{3} \mathrm{CCOO} \cdot$ radical with a $38.13 \mathrm{kcal} \mathrm{mol}^{-1}$ well depth. Reaction channels for the energized adduct $\mathrm{C}_{3} \mathrm{CCOO} \bullet *$ include dissociation back to reactants, stabilization to $\mathrm{C}_{3} \mathrm{CCOO}^{\bullet}$, isomerization by hydrogen transfer to the peroxy radical site via $\mathrm{TS} 1\left(E_{a}=23.82 \mathrm{kcal} \mathrm{mol}^{-1}\right)$ to form a $\mathrm{C}_{3} \cdot \mathrm{CCOOH}$ isomer $\left(\Delta H_{f}{ }^{\circ}{ }_{298}=-9.43\right.$ $\left.\mathrm{kcal} \mathrm{mol}{ }^{-1}\right)$, and dissociation to products $\left(\mathrm{C}_{3} \mathrm{CCHO}+\mathrm{OH}\right)$ via $\mathrm{TS} 2\left(E_{a}=41.61 \mathrm{kcal} \mathrm{mol}^{-}\right.$ ${ }^{1}$ ). The barrier for $\mathrm{C}_{3} \mathrm{CCOO} \bullet$ isomerization to $\mathrm{C}_{3} \cdot \mathrm{CCOOH}$ is calculated as 23.82 kcal $\mathrm{mol}^{-1}$, the chemically activated $\mathrm{C}_{3} \mathrm{CCOO}{ }^{*}$ adduct has sufficient energy for this isomerization to occur before it is stabilized or reacts back to reactants (reverse). Since the energy of TS3 is ca. $4 \mathrm{kcal} \mathrm{mol}{ }^{-1}$ lower than that of the entrance channel, the chemically activated $\mathrm{C}_{3} \mathrm{CCOO}{ }^{*}$ adduct can isomerize and dissociate to the 3,3dimethyloxetane +OH directly.

Figure 4.4 Potential energy diagram for $\mathrm{C}_{3} \mathrm{CC} \cdot+\mathrm{O}_{2}$ reaction system.

The energized $\mathrm{C}_{3} \cdot \mathrm{CCOOH}$ isomer undergo unimolecular reaction through several forward channels that are important to products or revert back to the peroxy isomer. Forward reactions are dissociation to 3,3-dimethyloxetane +OH via TS3 $\left(E_{a}=15.50 \mathrm{kcal}\right.$ $\left.\mathrm{mol}^{-1}\right), \beta$-scission to $\mathrm{C}_{2} \mathrm{C}=\mathrm{C}+\mathrm{CH}_{2} \mathrm{O}+\mathrm{OH}$ via TS4 $\left(E_{a}=25.38 \mathrm{kcal} \mathrm{mol}^{-1}\right)$, and another $\beta$-scission (elimination) to $\mathrm{C}=\mathrm{C}(\mathrm{C}) \mathrm{COOH}+\mathrm{CH}_{3}$ via $\mathrm{TS} 5\left(E_{a}=26.52 \mathrm{kcal} \mathrm{mol}^{-1}\right)$. The $\mathrm{C}_{3} \cdot \mathrm{CCOOH}$ isomer can also undergo a very interesting isomerization via TS6 ( $E_{a}=56.34$ $\mathrm{kcal} \mathrm{mol}^{-1}$ ) shifting a methyl group onto the $-\mathrm{CH}_{2} \bullet$ radical site forming a tertiary radical; but the high barrier and tight transition state make this channel unimportant. The
dominant channel of this hydroperoxy-neopentyl isomer is reverse reaction back to the peroxy isomer, with a barrier of only $5.64 \mathrm{kcal} \mathrm{mol}^{-1}$.

The 3,3-dimethyloxetane is an important product; it can undergo abstraction reaction to lose a secondary H atom bonded on a carbon in the ring structure, the radical formed will undergo ring opening via $\mathrm{C}-\mathrm{O}$ bond cleavage to form $\mathrm{C}_{3} \cdot \mathrm{CCHO}$ radical with a lower barrier ${ }^{83}$, or via $\mathrm{C}-\mathrm{C}$ bond cleavage to form $\mathrm{C}_{2} \mathrm{C}=\mathrm{COC} \cdot \operatorname{radical}\left(\mathrm{E}_{\mathrm{a}}=33.13\right.$ $\mathrm{kcal} / \mathrm{mol}$ ). The $\mathrm{C}_{3} \cdot \mathrm{CCHO}$ radical undergoes $\beta$-scission leading to the formation of isobutene $+\mathrm{HCO}\left(\mathrm{E}_{\mathrm{a}}=18.77 \mathrm{kcal} / \mathrm{mol}\right)$, or methacrolein $+\mathrm{CH}_{3}\left(\mathrm{E}_{\mathrm{a}}=27.33 \mathrm{kcal} / \mathrm{mol}\right)$; the $\mathrm{C}_{2} \mathrm{C}=\mathrm{COC} \cdot$ radical undergoes $\beta$-scission to form $\mathrm{CH}_{2} \mathrm{O}+\mathrm{C}_{2} \mathrm{C}=\mathrm{C} \cdot$ radical $\left(\mathrm{E}_{\mathrm{a}}=32.33\right.$ $\mathrm{kcal} / \mathrm{mol})$ which will undergo subsequently oxidation reactions. ${ }^{138}$

${ }^{\text {a }}$ From reference 7. ${ }^{\text {b }}$ From the principle of microscopic reversibility at 700 K .

The high-pressure limit rate constants for this $\mathrm{C}_{3} \mathrm{CC} \bullet+\mathrm{O}_{2}$ system are calculated from canonical transition state theory and fitted by three parameters $A_{\infty}, n$, and $E_{\mathrm{a}}$ over the temperature range from 298 to $2000 \mathrm{~K}, k_{\infty}=A T^{n} \exp \left(-E_{\alpha} / R T\right)$, by the THERMKIN ${ }^{72}$
program. These are important kinetic parameters and are used as input for QRRK and Master equation analysis. The values of these parameters are listed in Table 4.6, and the thermodynamic analysis for reactions of neopentyl oxidation by THERMKIN are illustrated in Table B. 3 .

Figures 4.5 Calculated temperature dependent rate constants for chemical activated $\mathrm{C}_{3} \mathrm{CC} \cdot+\mathrm{O}_{2}$ system at $\mathrm{P}=1 \mathrm{~atm}$.

The calculated temperature dependent rate constants for chemically activated $\mathrm{C}_{3} \mathrm{CC} \cdot+\mathrm{O}_{2}$ reaction system from 300 to 1500 K at 1 atm are illustrated in Figure 4.5. The dominant product-channel for $\mathrm{C}_{3} \mathrm{CC} \cdot+\mathrm{O}_{2}$ is stabilization to $\mathrm{C}_{3} \mathrm{CCOO} \cdot$ below 1000 K. The forward and reverse isomerization and reverse reaction (dissociation) occur
rapidly; the isomerization and the epoxide formation steps have relatively tight transition states with Arrhenius pre-exponential factors of ca. $10^{11} \mathrm{~s}^{-1}$ between $300 \sim 1000 \mathrm{~K}$ respectively, and the reverse isomerization is fast because of the very low barrier (5.64 kcal $\mathrm{mol}^{-1}$ ). At the low temperatures of $700 \sim 800 \mathrm{~K}$, the stabilization and isomerization are the dominant channels with $3.1 \sim 10.3 \%$ of total forward reaction forming 3,3dimethyloxetane +OH . Reverse reaction and dissociation to 3,3-dimethyloxetane +OH are the important reactions of the $\mathrm{C}_{3} \cdot \mathrm{CCOOH}$ adduct above 1000 K ; this results in falloff by 1000 K .

Figures 4.6 Calculated pressure dependent rate constants for chemical activated $\mathrm{C}_{3} \mathrm{CC}$ • $+\mathrm{O}_{2}$ system at $\mathrm{T}=300 \mathrm{~K}$.

Figures 4.6 and 4.7 illustrate the pressure dependence for the rate constants ( $\log k$ vs $P$ ) of the chemically activated reactions, at 300 K and 1000 K . Stabilization to
$\mathrm{C}_{3} \mathrm{CCOO} \cdot$ is the dominant channel over all pressures at 300 K ; it is also the dominant product channel when pressure is over 1 atm at 1000 K . When pressure is below 1 atm , the dissociation back to $\mathrm{C}_{3} \mathrm{CC} \cdot+\mathrm{O}_{2}$ becomes the dominant channel at 1000 K , with the formation of 3,3-dimethyloxetane +OH competitive over the entire temperature range. The rate constants of other product channels decrease as the pressure increases. The next important reactions are formation of isobutene $+\mathrm{CH}_{2} \mathrm{O}+\mathrm{OH}$ and $\mathrm{C}=\mathrm{C}(\mathrm{C}) \mathrm{COOH}+\mathrm{CH}_{3}$, which have similar rates and are lower than the epoxide +OH channel over the entire temperature range.

Figures 4.7 Calculated pressure dependent rate constants for chemical activated $\mathrm{C}_{3} \mathrm{CC} \cdot$ $+\mathrm{O}_{2}$ system at $\mathrm{T}=1000 \mathrm{~K}$.
4.4.3.2 Dissociation of Adduct. Stabilization of the neopentyl peroxy adduct is an important product in the chemical activation reaction system below 1000 K . There are two important reactions of stabilized $\mathrm{C}_{3} \mathrm{CCOO} \cdot$ radical at atmospheric pressure as shown in Figure 4.8. One is isomerization to $\mathrm{C}_{3} \cdot \mathrm{CCOOH}$, and this channel is competitive with dissociation back to reactants $\mathrm{C}_{3} \mathrm{CC} \bullet+\mathrm{O}_{2}$ above the temperature of 800 K . The isomer $\mathrm{C}_{3} \cdot \mathrm{CCOOH}$ has a very low barrier for reverse reaction and thus the neopentyl peroxy radical and the hydroperoxy-neopentyl isomer will exist in a quasi equilibrium, where the lower enthalpy peroxy radical will be the dominant isomer.

Figure 4.8 Calculated temperature dependent dissociation rate constants for $\mathrm{C}_{3} \mathrm{CCOO} \cdot$ at $\mathrm{P}=1 \mathrm{~atm}$.

There are four important reactions of stabilized $\mathrm{C}_{3} \cdot \mathrm{CCOOH}$ radical at atmospheric pressure as shown in Figure 4.9. The lowest barrier is the isomerization back to $\mathrm{C}_{3} \mathrm{CCOO}$ •, but the dissociation to 3,3-dimethyloxetane +OH is competitive with the
isomerization over the entire temperature range. The reaction channels for dissociation to $\mathrm{C}_{2} \mathrm{C}=\mathrm{C}+\mathrm{CH}_{2} \mathrm{O}+\mathrm{OH}$ and dissociation to $\mathrm{C}=\mathrm{C}(\mathrm{C}) \mathrm{COOH}+\mathrm{CH}_{3}$ are similar and several orders of magnitude lower than the epoxide +OH channel over temperature of $300 \sim$ 1500 K.

Figure 4.9 Calculated temperature dependent dissociation rate constants for $\mathrm{C}_{3} \cdot \mathrm{CCOOH}$ at $\mathrm{P}=1 \mathrm{~atm}$.

The master equation analysis ${ }^{26}$ for isomerization or dissociation from stabilized adducts does not include reactions past the adjacent well(s), so it is necessary to account for further reaction of these products in the numerical kinetic integration (Chemkin analysis).
4.4.3.3 $\mathbf{C}_{3} \cdot \mathbf{C C O O H}+\mathbf{O}_{2}$. The potential energy surface for addition of a second $\mathrm{O}_{2}$ to hydroperoxy-neopentyl radical $\left(\mathrm{C}_{3} \cdot \mathrm{CCOOH}\right)$ calculated at the B3LYP/6-311++G(3df,2p) level is shown in Figure 4.10.

Figure 4.10 Potential energy diagram for $\mathrm{C}_{3} \cdot \mathrm{CCOOH}+\mathrm{O}_{2}$ reaction system.

The $\mathrm{C}_{3} \cdot \mathrm{CCOOH}$ reacts with $\mathrm{O}_{2}$ to form a hydroperoxide-peroxy $\mathrm{C}_{2} \mathrm{C}(\mathrm{OOH}) \mathrm{COO} \cdot$ with a $32.96 \mathrm{kcal} \mathrm{mol}^{-1}$ well depth. Reaction channels for the chemically activated adduct $\mathrm{C}_{2} \mathrm{C}(\mathrm{OOH}) \mathrm{COO}^{*}$ include dissociation back to reactants, stabilization to $\mathrm{C}_{2} \mathrm{C}(\mathrm{OOH}) \mathrm{COO}$, isomerization via hydrogen shift via $\mathrm{TS} 7\left(E_{a}=22.58 \mathrm{kcal} \mathrm{mol}^{-1}\right)$ to form a dihydroperoxide isomer $\mathrm{C}_{2} \cdot \mathrm{C}(\mathrm{COOH})_{2}\left(\Delta H_{f}{ }^{\circ} 298=-25.14 \mathrm{kcal} \mathrm{mol}^{-1}\right)$, and dissociation to products $\left(\mathrm{C}_{3} \mathrm{CCHO}+\mathrm{OH}\right)$ via two different transition states: TS8 $\left(E_{a}=\right.$ $22.40 \mathrm{kcal} \mathrm{mol}^{-1}$ ) and TS8A ( $E_{a}=41.23 \mathrm{kcal} \mathrm{mol}^{-1}$ ). The dihydroperoxide isomer
$\mathrm{C}_{2} \cdot \mathrm{C}(\mathrm{COOH})_{2}$ undergoes dissociation to 3-methyl,3-hydroperoxideoxetane +OH via TS9 ( $E_{a}=14.35 \mathrm{kcal} \mathrm{mol}^{-1}$ ), $\beta$-scission to generate a hydroperoxide olefin $\mathrm{C}=\mathrm{C}(\mathrm{C}) \mathrm{COOH}$ and $\mathrm{CH}_{2} \mathrm{O}+\mathrm{OH}$ via $\operatorname{TS10}\left(E_{a}=17.34 \mathrm{kcal} \mathrm{mol}^{-1}\right)$. The stabilized $\mathrm{C}_{2} \mathrm{C}(\mathrm{OOH}) \mathrm{COO} \cdot$ peroxy undergoes homolytic dissociation via cleavage of the weak $\mathrm{O}-\mathrm{O}$ bond with barrier of $43.03 \mathrm{kcal} \mathrm{mol}^{-1}$. The stable vinyl hydroperoxide produced will also undergo homolytic cleavage of the weak $\mathrm{O}-\mathrm{O}$ bond in the peroxide moiety to generate OH and vinyl alkoxy (chain branching reaction), serving to accelerate the oxidation process. The vinyl alkoxy radical is an important reaction to form 2-methyl-2-propenal $(\mathrm{C}=\mathrm{C}(\mathrm{C}) \mathrm{CHO})$ which was identified as an important product from neopentyl radical oxidation. ${ }^{105}$

A number of the reaction channels for $\mathrm{C}_{2} \mathrm{C}(\mathrm{COOH}) \mathrm{COO} \bullet *$ adduct are similar to those of $\mathrm{C}_{3} \mathrm{CCOO}^{*}$ adduct due to the similarity between the two adduct structures. Table 4.7 lists calculated reaction enthalpies for similar reaction channels in Figure 4.4 and Figure 4.10. In Table 4.7, the barriers for the corresponding isomerization channels and dissociation channels in two reaction systems show agreement, especially for the channels with tight transition states (ring formation).

|  |  |  |  | TS8 | 22.93 | 22.40 |  |

${ }^{\text {a }}$ Units in $\mathrm{kcal} / \mathrm{mol}$. ${ }^{\text {b }}$ Corrected reaction enthalpies according to the trend calculated from three different levels for the similar reaction channels.

In order to obtain more accurate reaction enthalpies in this second $\mathrm{O}_{2}$ addition system than those from the DFT calculations, we evaluate the deviation of enthalpies
between the DFT and the CBS-Q levels, and then correct the corresponding DFT level reaction enthalpies to CBS-Q level for these oxygenated species. The barriers calculated from the B3LYP/6-311++G(3df,2p) level in Figure 4.10 are corrected as 22.98, 15.72, 14.93, and $40.78 \mathrm{kcal} \mathrm{mol}^{-1}$ for TS7, TS9, TS10, and TS8A, respectively. The correction is $0.4 \sim 1.4 \mathrm{kcal} \mathrm{mol}^{-1}$ for the reactions with ring- formation transition states, and is 2.4 $\mathrm{kcal} \mathrm{mol}{ }^{-1}$ for the dissociation of $-\mathrm{CH}_{2} \mathrm{OOH}$ group with TS 10 .

One new important channel in Figure 4.10 , that is not in the $\mathrm{C}_{3} \mathrm{CC} \bullet+\mathrm{O}_{2}$ system (Figure 4.4), is the exothermic formation of $\mathrm{C}_{2} \mathrm{C}(\mathrm{COOH}) \mathrm{CHO}+\mathrm{OH}$ via a 6-member ring transition state (TS8) with a $22.40 \mathrm{kcal} \mathrm{mol}^{-1}$ barrier. In TS8, the peroxy radical abstracts the weakly bonded H atom in the $-\mathrm{CH}_{2} \mathrm{OOH}$ group; this $\mathrm{H}-\mathrm{C}\left(\mathrm{C}_{2}\right) \mathrm{HOOH}$ bond is weak because, as the H atom is leaving, a strong carbonyl bond (gain of $\sim 80 \mathrm{kcal} \mathrm{mol}^{-1}$ ) is forming with the weak $\mathrm{O}-\mathrm{OH}$ bond $\left(\sim 45 \mathrm{kcal} \mathrm{mol}^{-1}\right)$ cleaving.

The chemical activated $\left[\mathrm{C}_{2} \mathrm{C}(\mathrm{COOH}) \mathrm{CHO}\right]^{*}$ species can undergo dissociation to cleave the weak $\mathrm{RO}-\mathrm{OH}$ bond to form a 2-methyl isopropanal-2-methyoxy radical $\left(\mathrm{C}_{2} \mathrm{C}(\mathrm{CHO}) \mathrm{CH}_{2} \mathrm{O} \cdot\right.$ ) plus a second OH (overall reaction $\mathrm{C}_{3} \cdot \mathrm{CCOOH}+\mathrm{O}_{2} \rightarrow$ $\mathrm{C}_{2} \mathrm{C}(\mathrm{CHO}) \mathrm{CH}_{2} \mathrm{O} \cdot+2 \mathrm{OH}$ ), or it can be stabilized. While the branching ratio to the two products is a function of temperature, it is calculated to be near $1: 1$ at the conditions modeled in this study. The $\left[\mathrm{C}_{2} \mathrm{C}(\mathrm{COOH}) \mathrm{CHO}\right]^{*}$ species has ca. $48 \mathrm{kcal} \mathrm{mol}^{-1}$ activation energy at the transition state point.

The stabilized $\mathrm{C}_{2} \mathrm{C}(\mathrm{COOH}) \mathrm{CHO}$ can undergo bimolecular reaction (abstraction) and the product radicals can dissociate by low energy $\beta$-scission. For example, the weakly bonded H atom will be abstracted to form $\mathrm{C}_{2} \mathrm{C}(\mathrm{COOH}) \mathrm{C} \cdot=\mathrm{O}$ radical, which will dissociate to CO and $\mathrm{C}_{2} \mathrm{C} \cdot \mathrm{COOH}$, which will further dissociate to isobutene $+\mathrm{HO}_{2}$.

These are important chain branching channels at low temperature and also contribute to OH and $\mathrm{HO}_{2}$ product formation.

The 2-methyl isopropanal-2-methyoxy radical $\mathrm{C}_{2} \mathrm{C}(\mathrm{CHO}) \mathrm{CH}_{2} \mathrm{O}$ • will undergo $\beta$ scission to either $\mathrm{C}_{2} \mathrm{C} \cdot(\mathrm{CHO})+\mathrm{CH}_{2} \mathrm{O}$ via TS 11 , or to $\mathrm{C}_{2} \mathrm{C}(\mathrm{CHO})_{2}+\mathrm{H}$ via TS 12 as outlined in the reaction mechanism scheme. The $\mathrm{C}_{2} \mathrm{C} \cdot(\mathrm{CHO})$ radical will undergo the $\beta$ scission to $\mathrm{C}=\mathrm{CC}+\mathrm{HCO}$ via TS 13 A , or $\mathrm{C}=\mathrm{C}(\mathrm{C}) \mathrm{CHO}+\mathrm{H}$ via TS 13 , which are important products that were observed in neopentane oxidation. ${ }^{113}$

${ }^{2}$ The A factor is by generic reaction or estimated by reverse reaction and microscopic reversibility. ${ }^{\mathrm{b}}$ Estimated as the sum of reverse $\mathrm{E}_{\mathrm{a}}$ and $\Delta H_{\mathrm{rxn}}{ }^{\circ}$.

The high-pressure limit rate constants for the $\mathrm{C}_{3} \cdot \mathrm{CCOOH}+\mathrm{O}_{2}$ system are fitted by three parameters $A_{\infty}, n$, and $E_{\mathrm{a}}$ over the temperature range from 298 to 2000 K and these fits along with data are listed vs. temperature in Appendix Table B.3. Important
input kinetic parameters for QRRK and Master equation analysis for this system are listed in Table 4.8.

The calculated temperature dependent rate constants for the chemical activated $\mathrm{C}_{3} \cdot \mathrm{CCOOH}+\mathrm{O}_{2}$ system are illustrated in Figure 4.11 for conditions of 300 to 1500 K at 1 atm . The dominant product for $\mathrm{C}_{3} \cdot \mathrm{CCOOH}+\mathrm{O}_{2}$ is stabilization to $\mathrm{C}_{2} \mathrm{C}(\mathrm{OOH}) \mathrm{COO} \bullet$ below 800 K , but reverse reaction becomes the dominant channel above 800 K .

Figure 4.11 Calculated temperature dependent rate constants for chemical activated $\mathrm{C}_{3} \cdot \mathrm{CCOOH}+\mathrm{O}_{2}$ system at $\mathrm{P}=1 \mathrm{~atm}$.

The most important new product channel for stabilized $\mathrm{C}_{2} \mathrm{C}(\mathrm{OOH}) \mathrm{COO} \cdot$ radical at atmospheric pressure is the formation of $\left[\mathrm{C}_{2} \mathrm{C}(\mathrm{COOH}) \mathrm{CHO}\right]^{*}+\mathrm{OH}$ via TS 8 as shown in Figure 4.11 , this reaction is competitive with the reverse channel to $\mathrm{C}_{3} \cdot \mathrm{CCOOH}+\mathrm{O}_{2}$
below 800 K . The dissociation channel (chain branching) of $\left[\mathrm{C}_{2} \mathrm{C}(\mathrm{COOH}) \mathrm{CHO}\right]^{*}$ to $\mathrm{C}_{2} \mathrm{C}(\mathrm{CO} \cdot) \mathrm{CHO}+2 \mathrm{OH}$ becomes slightly dominant above 800 K ; it is the important forward channel to products and is an important chain branching step at low and intermediate temperatures. The isomerization to $\mathrm{C}_{2} \cdot \mathrm{C}(\mathrm{COOH})_{2}$ is the next important forward channel below 600 K , and the homolytic cleavage of the weak $\mathrm{RO}-\mathrm{OH}$ bond in $\mathrm{C}_{2} \mathrm{C}(\mathrm{OOH}) \mathrm{COO} \cdot($ also a chain branching path $)$ becomes important above 600 K .

A plot of $\log \mathrm{k}$ vs pressure for the $\mathrm{C}_{3} \cdot \mathrm{CCOOH}+\mathrm{O}_{2}$ system at 700 K is shown in Figure 4.12, which illustrates that stabilization to the peroxy radical and reverse reaction channels are dominant at all pressures. The dissociation to $\mathrm{C}_{2} \mathrm{C}(\mathrm{COOH}) \mathrm{CHO}+\mathrm{OH}$ and $\mathrm{C}_{2} \mathrm{C}(\mathrm{CHO}) \mathrm{CH}_{2} \mathrm{O} \cdot+2 \mathrm{OH}$ are the most important forward channels at all these pressures.

Figure 4.12 Calculated pressure dependent rate constants for chemical activated $\mathrm{C}_{3} \cdot \mathrm{CCOOH}+\mathrm{O}_{2}$ system at $\mathrm{T}=700 \mathrm{~K}$.

### 4.4.4 Unimolecular Dissociation of Neopentyl Radical

At higher reaction temperatures, the neopentyl radical will undergo unimolecular dissociation to isobutene + methyl radical in competition with the $\mathrm{R} \cdot+\mathrm{O}_{2}$ association reaction. The rate constant for unimolecular dissociation is calculated as $k=10^{13.68} \exp (-$ $\left.30.84 \mathrm{kcal} \mathrm{mol}^{-1} / \mathrm{RT}\right)^{-1}$ at the CBS-Q level. It shows good agreement with the experimentally determined rate constant by Slagle et al, ${ }^{139} k=10^{13.9} \exp (-30.9 \pm 1.0 \mathrm{kcal}$ $\left.\mathrm{mol}^{-1} / \mathrm{RT}\right)^{-1}$. The importance of this neopentyl radical unimolecular decomposition is also evaluated.

The OH radical generated by the neopentyl oxidation reactions and the methyl radical from the $\beta$-scission reaction above will add to isobutene forming new isobutene adducts: $\mathrm{C}_{3} \cdot \mathrm{COH}, \mathrm{C}_{2} \mathrm{C} \cdot \mathrm{COH}$ and $\mathrm{C}_{2} \mathrm{C} \cdot \mathrm{CC}$. These OH and $\mathrm{CH}_{3}$ addition reactions and the subsequent $\mathrm{O}_{2}$ addition reactions to these adducts have been calculated and included in our mechanism, but these reactions have little contribution to the OH formation profile. The reaction pathways and high pressure limit rate constants for the oxidation of these isobutene adducts will be discussed in the following chapter on modeling experimental $\mathrm{HO}_{2}$ formation profiles in the neopentyl oxidation system.

### 4.4.5 Model and Comparison with Experimental Result

A detailed reaction mechanism (258 reactions of which approximately 170 reactions are pressure dependent, 115 species) for the initial neopentyl oxidation is assembled in Appendix Table B.4, and the CHEMKIN II interpreter and integrator (version 3.1) ${ }^{140}$ is used to model the experimental OH formation profile for the reaction time of $0 \sim 3 \mathrm{~ms}$. Abstraction reactions are not considered pressure dependent and therefore do not require fall-off analysis. Abstraction reactions of $\mathrm{O}, \mathrm{OH}, \mathrm{HO}_{2}$, and $\mathrm{R} \cdot$ radicals are taken from
evaluated literature wherever possible. A procedure from Dean and Bozzelli ${ }^{141}$ is used to estimate abstraction rate constants by $\mathrm{H}, \mathrm{O}, \mathrm{OH}$, and $\mathrm{CH}_{3}$ radicals when no literature data are available.

Figure 4.13 Comparison of the present model with the experimental OH LIF measurements of Hughes et al.

The time dependence of OH radical formation profile predicted by our reaction mechanism compared with experimental data published by Hughes et al. ${ }^{105}$ is shown in Figure 4.13. The experiment was performed at $700 \mathrm{~K}, 613.3$ torr, with $\mathrm{O}_{2}$ pressure of 63.3 torr and $\mathrm{C}_{3} \mathrm{CC} \cdot$ radical concentration of $3 \times 10^{11}$ molecule $\mathrm{cm}^{-3}$. The solid curve in

Figure 4.13 represents our modeling result for the OH profile, and it shows good agreement with experimental data of Hughes et al. The reactions from the addition of the second $\mathrm{O}_{2},\left(\mathrm{C}_{3} \cdot \mathrm{CCOOH}+\mathrm{O}_{2}\right)$ contributes 0.9 to $6.4 \%$ of the total predicated OH formation from the model. Sensitivity analysis on the OH formation at the experimental temperature and pressure is shown in Figure 4.14. The reaction channel for the formation of 3,3-dimethyloxetane +OH is calculated to have the highest sensitivity for the formation of the OH radical, the isomerization to $\mathrm{C}_{3} \cdot \mathrm{CCOOH}$ from $\mathrm{C}_{3} \mathrm{CCOO} \cdot$ radical is the next, the well depth of the chemical activation reaction of $\mathrm{C}_{3} \mathrm{CC} \cdot+\mathrm{OH}$ for formation of neopentyl peroxy and 3,3-dimethyloxetane +OH and the unimolecular decomposition of neopentyliodide radical are also important.

Figure 4.14 Sensitivity analysis on OH formation at $\mathrm{T}=700 \mathrm{~K}$ and $\mathrm{P}=613.3$ torr.

The loss of OH radical, is most sensitive to wall reaction, and the unimolecular decomposition of neopentyl radical to isobutene $+\mathrm{CH}_{3}$ is also important, since it results in the loss of the OH precursor. The entropy of TS3 for the formation of 3,3dimethyloxetane +OH is calculated as $98.04 \mathrm{cal} / \mathrm{mol}$, and it is increased by $1.5 \mathrm{cal} \mathrm{mol}^{-1}$ $\mathrm{K}^{-1}$ to fit the OH formation profile with reaction time.

Overall, there are several major reactions responsible for the OH formation: (i) Dissociation of hydroperoxy-neopentyl radical to 3,3-dimethyloxetane +OH ; (ii) The addition of a second $\mathrm{O}_{2}$ to hydroperoxy-neopentyl radical with isomerization and subsequent dissociation reactions; and (iii) Reactions of $\mathrm{CH}_{3}$ from neopentyl dissociation. Importance of these reaction paths changes with concentrations, pressure and temperature. At a pressure of 613.3 torr and a temperature of 700 K , the formation of 3,3dimethyloxetane +OH is by far the most important channel to form OH radical.

### 4.5 Summary

Thermochemical properties of the neopentyl radical + oxygen reaction system and the hydroperoxy neopentyl radical $+\mathrm{O}_{2}$ reaction system are calculated using ab initio CBS-Q and density functional B3LYP/6-311++G(3df,2p) methods. The barriers for the isomerization of neopentyl peroxy and subsequent epoxide formation reactions are calculated as 23.82 and $15.50 \mathrm{kcal} / \mathrm{mol}$, respectively. Kinetic parameters for intermediate and product formation channels are calculated versus temperature and pressure. A mechanism describing reaction paths and kinetic parameters for the initial steps in the neopentyl oxidation reaction system is developed to model the experimental OH formation profile. Second $\mathrm{O}_{2}$ addition to the hydroperoxy neopentyl radical has a minor
contribution to the OH profile under the modeled condition, but can be important to chain branching. Several reactions are predicted to be important for OH formation profile. Thermodynamic equilibrium on the reactions of $\mathrm{C}_{3} \mathrm{CCOO} \bullet \Leftrightarrow \mathrm{C}_{3} \cdot \mathrm{CCOOH}$ and reactions $\left(\mathrm{C}_{3} \cdot \mathrm{CCOOH} \rightarrow\right.$ 3,3-dimethyloxetane $\left.+\mathrm{OH}, \mathrm{C}_{2} \mathrm{C}=\mathrm{C}+\mathrm{CH}_{2} \mathrm{O}+\mathrm{OH}\right)$, serve to control oxidation rate in this 700 K and 613.3 torr reaction system.

## CHAPTER 5

## KINETIC ANALYSIS OF 2-HYDROXY-1,1-DIMETHYLETHYL, 2-HYDROXY-2-METHYLPROPYL, AND 1,1-DIMETHYLPROPYL RADICALS OXIDATION

### 5.1 Overview

The reaction systems of 2-hydroxy-1,1-dimethylethyl, 2-hydroxy-2-methylpropyl, and 1,1-dimethylpropyl radicals plus $\mathrm{O}_{2}$, which are secondary reactions in neopentyl radical + $\mathrm{O}_{2}$ oxidation system, are analyzed with $a b$ initio and density functional calculations to evaluate reaction paths and kinetics important in neopentyl oxidation. Enthalpies of formation ( $\Delta H_{f}^{o}{ }_{298}$ ) are determined using isodesmic reaction analysis at the CBS-Q//B3LYP/6-31G(d,p) level. The entropies ( $S^{\circ}{ }_{298}$ ) and heat capacities $C_{p}(T)$ 's $(0 \leq T / \mathrm{K} \leq$ 1500) from vibrational, translational, and external rotational contributions are calculated using statistical mechanics based on the vibrational frequencies and structures obtained from the density functional study. The hindered internal rotor contributions to $S^{0}{ }_{298}$ and $C_{P}(T)$ 's are calculated from the analysis of rotational potentials. $\Delta H_{f}^{o} 298$ values for radicals $\mathrm{C}_{2} \mathrm{C} \cdot \mathrm{COH}, \mathrm{C}_{2} \mathrm{C}(\mathrm{OO} \cdot) \mathrm{COH}, \mathrm{C}_{3} \cdot \mathrm{COH}, \mathrm{C}_{2} \mathrm{C}(\mathrm{OH}) \mathrm{COO} \cdot$, and $\mathrm{C}_{2} \mathrm{C}(\mathrm{OO} \cdot) \mathrm{CC}$ are calculated as $-22.22,-62.71,-24.12,-61.76$, and $-33.58 \mathrm{kcal} \mathrm{mol}^{-1}$ at the CBS-QB3 level. The potential energy surfaces of the three reaction systems are calculated at the CBS-QB3 level. Rate constants are calculated as function of pressure and temperature using quantum Rice-Ramsperger-Kassel (QRRK) analysis for $k(\mathrm{E})$ and master equation for pressure fall-off. Kinetic parameters for intermediate and product formation channels of above reaction systems are presented versus temperature and pressure. An elementary reaction mechanism is constructed to model experimental $\mathrm{HO}_{2}$ formation profiles at different $\mathrm{O}_{2}$ concentrations in the neopentane oxidation reactions.

### 5.2 Background

The reactions of neopentyl radical with molecular oxygen have been investigated for modeling the time dependence of the OH formation profile based on ab initio and density functional computation methods in Chapter 4. Taatjes et al. ${ }^{103}$ recently measured the time-resolved production of $\mathrm{HO}_{2}$ and OH in pulsed-photolytic Cl -initiated oxidation of neopentane between 573 and 750 K . They reported that: (a) significant $\mathrm{HO}_{2}$ formation is observed above 623 K , where the formation of $\mathrm{HO}_{2}$ increases with increasing temperature; (b) the $\mathrm{HO}_{2}$ produced also increases with increasing $\mathrm{O}_{2}$ at 673 K ; (c) their OH measurements are especially sensitive to the direct pathways from $\mathrm{R}+\mathrm{O}_{2}$ to QOOH and to $\mathrm{OH}+3,3$-dimethyloxetane. They also developed a kinetic model based on the comparison with their previous time-dependent master equation calculation of analogous processes in the reaction of n-propyl with $\mathrm{O}_{2}$. Taatjes et. al performed B3LYP/6-31G(d,p) calculations for the stationary points on the neopentyl $+\mathrm{O}_{2}$ system (surface) and adjusted this DFT data by the difference between B3LYP/6-31G(d,p) and QCISD(T)/6$311++\mathrm{G}(3 \mathrm{df}, 2 \mathrm{pd})$ energies from their study on the n -propyl $+\mathrm{O}_{2}$ system. The well depth for neopentyl $+\mathrm{O}_{2}$ is estimated as $35 \mathrm{kcal} \mathrm{mol}^{-1}$.

The results of Taatjes et. al and from Chapter 4 both show that there is no direct neopentyl $+\mathrm{O}_{2}$ reaction to form $\mathrm{HO}_{2}$ that is important. The $\mathrm{HO}_{2}$ formation is therefore a secondary reaction product. The most significant reaction path producing $\mathrm{HO}_{2}$ in the mechanism of Taatjes et. al's is identified to be the reaction of OH with neopentylperoxy to form $\mathrm{HO}_{2}$ and neopentoxy radical. This radical-radical association reaction is expected to be barrier-less and slightly exothermic, and their estimate of the rate constant is taken from the rate of generic reaction $\mathrm{CF}_{3} \mathrm{OO} \cdot+\mathrm{OH}$. Their model comparison with
experimental $\mathrm{HO}_{2}$ concentration vs. time profiles at 673 K for three $\mathrm{O}_{2}$ concentrations show good agreement; but did not qualitatively reproduce the continued production of $\mathrm{HO}_{2}$ at longer times. They suggest that inclusion of additional reaction steps for the initial neopentyl $+\mathrm{O}_{2}$ products might improve the overall agreement.

The important initial, reactive products in the neopentyl radical reaction with $\mathrm{O}_{2}$ are: neopentyl peroxy radical, OH radical, plus methyl radical and isobutene from $\mathrm{CH}_{3}$ elimination of neopentyl radical. The addition of $\mathrm{CH}_{3}$ and OH to the isobutene can form three new radical products, which will undergo further oxidation by reaction with $\mathrm{O}_{2}$. These radicals are 2-hydroxy-1,1-dimethylethyl radical, 2-hydroxy-2-methylpropyl radical, and 1,1-dimethylpropyl radical.

An elementary mechanism based on $a b$ initio and density functional calculations and our earlier mechanism ${ }^{142}$ for modeling OH formation is constructed to model $\mathrm{HO}_{2}$ formation profiles in this study. The mechanism includes OH addition to isobutene at both of the $\mathrm{CD} / \mathrm{H} 2$ and $\mathrm{CD} / \mathrm{C} 2$ carbon atoms and $\mathrm{CH}_{3}$ addition to the $\mathrm{CD} / \mathrm{H} 2$ carbon along with $\mathrm{O}_{2}$ association reactions with these isobutene adducts. The model is shown to predict well for the experimental time-dependent formation of $\mathrm{HO}_{2}$ profile at different $\mathrm{O}_{2}$ concentrations reported by Taatjes et. al ${ }^{103}$, and the important reaction pathways that effect on production of $\mathrm{HO}_{2}$ radical in the mechanism are illustrated.

### 5.3 Calculation Method

The geometries of reactants, intermediates, transition states and products in neopentyl + $\mathrm{O}_{2}$ reaction system are calculated at the $\mathrm{B} 3 \mathrm{LYP} / 6-31 \mathrm{G}(\mathrm{d}, \mathrm{p})$ level using the Gaussian 98 program. ${ }^{32}$ The optimized structure parameters are then used to obtain total electronic
energies at the B3LYP/6-311++G(3df,2p) and CBS-Q//B3LYP/6-31G(d,p) single point levels of calculation. Contributions from vibrational, translational, external rotational, and electronic to entropies and heat capacities are calculated by statistical mechanics based on the vibrational frequencies and moments of inertia from the DFT optimized structures. The torsion frequencies are omitted in calculation of $S^{0}{ }_{298}$ and $C_{p}(T)$ 's, and their contributions are replaced with values from the analysis of internal rotations. The $\Delta H_{\mathrm{f}}^{\mathrm{o}} 298$ values for reactants, intermediate and products are calculated using total energies from ab initio CBS-Q and DFT calculations and use of isodesmic reactions with group balance when possible. The $\Delta H_{\mathrm{f}}{ }^{\circ} 298$ values of transition state structures are calculated by the $\Delta H_{\mathrm{f}}{ }^{\circ} 298$ of stable radical adducts from working isodesmic reaction analysis, plus the difference of total energies between transition states and radical adducts at the CBS-Q level.

Unimolecular dissociation and isomerization reactions of the chemically activated and stabilized adducts resulting from addition or combination reactions are analyzed by first constructing potential energy diagrams for the reaction system. DFT and ab initio calculations are then used to calculate transition state structures and activation energy for isomerization, $\beta$-scission, and dissociation reactions. The enthalpies and entropies of the reactants and transition state structures are treated with conventional transition state theory to calculate Arrhenius pre-exponential factors and energies of activation, which result in high pressure limit rate constants ( $k_{\infty}$ ) as function of temperature.

Branching ratios of the energized adduct to stabilization and product channels are then calculated using multi-frequency Quantum Rice-Rampsperger-Kassel (QRRK) analysis for $k(E)^{66,115}$ with the steady-state assumption on the energized adduct(s) in
combination with a master equation analysis for fall-off. ${ }^{26}$ A 0.5 kcal energy grain used to obtain rate constants as a function of temperature and pressure for chemical activation and dissociation reactions. $(\Delta E)^{\circ}$ down of $570 \mathrm{cal} \mathrm{mol}^{-1}$ is used in the master equation analysis with helium as the third body. Lennard-Jones parameters, $\sigma$ (Angstroms) and $\varepsilon / \kappa$ (Kelvins), are obtained from tabulations ${ }^{90}$ and from an estimation method based on molar volumes and compressibility.

### 5.4 Results and Discussion

### 5.4.1 Geometries

The geometry optimizations for the reactants, transition states, adducts, and products in the isobutene- OH and isobutene $-\mathrm{CH}_{3}$ adducts oxidation systems are performed at the B3LYP/6-31G(d,p) level. The optimized structural parameters for 41 species including transition state structures are listed in Appendix Table C.1. The corresponding un-scaled vibrational frequencies and moments of inertia are listed in Table C.2. The notations of several important reactants and products in these systems are defined as: $\mathrm{C}_{2} \cdot \mathrm{COH}$ (2-hydroxy-1,1-dimethylethyl), $\quad \mathrm{C}_{3} \cdot \mathrm{COH} \quad$ (2-hydroxy-2-methylpropyl), $\quad \mathrm{C}_{2} \cdot \mathrm{CCC}$ (1,1dimethylpropyl), $\quad \mathrm{C}_{2} \mathrm{C}=\mathrm{COH} \quad$ (2-methyl-1-propen-1-ol), $\quad \mathrm{C}=\mathrm{C}(\mathrm{C}) \mathrm{COH} \quad$ (2-methyl-2-propen-1-ol), $\quad \mathrm{C}=\mathrm{C}(\mathrm{C}) \mathrm{OH}$ (1-propen-2-ol), $\mathrm{C}_{2} \mathrm{C}=\mathrm{O}$ (acetone), $\mathrm{C}=\mathrm{C}(\mathrm{C}) \mathrm{CC}$ (2-methyl-1butene), $\mathrm{C}_{2} \mathrm{C}=\mathrm{CC}$ (2-methyl-2-butene), and $\mathrm{C}_{2} \mathrm{CyCOCC}$ (2,2-dimethyl-oxetane). The transition states of important reactions in these oxidation systems are identified as follows:

## Peroxy radical isomerization:

$\mathrm{C}_{2} \mathrm{C}\left(\mathrm{OO} \bullet \cdot \mathrm{COH} \rightarrow \mathrm{TS} 14 \rightarrow \mathrm{C}_{2} \mathrm{C}(\mathrm{OOH}) \mathrm{CH}_{2} \mathrm{O} \bullet\right.$
$\mathrm{C}_{2} \mathrm{C}(\mathrm{OO} \cdot) \mathrm{COH} \rightarrow \mathrm{TS} 15 \rightarrow \mathrm{C}_{2} \cdot \mathrm{C}(\mathrm{OOH}) \mathrm{COH}$
$\mathrm{C}_{2} \mathrm{C}(\mathrm{OO} \cdot) \mathrm{COH} \rightarrow \mathrm{TS} 16 \rightarrow \mathrm{C}_{2} \mathrm{C}(\mathrm{OOH}) \mathrm{C} \cdot \mathrm{OH}$
$\mathrm{C}_{2} \mathrm{C}(\mathrm{OH}) \mathrm{COO} \rightarrow \mathrm{TS} 22 \rightarrow \mathrm{C}_{2} \mathrm{C}\left(\mathrm{O}^{\bullet}\right) \mathrm{COOH}$
$\mathrm{C}_{2} \mathrm{C}(\mathrm{OH}) \mathrm{COO} \bullet \mathrm{TS} 23 \rightarrow \mathrm{C}_{2} \cdot \mathrm{C}(\mathrm{OH}) \mathrm{COOH}$
$\mathrm{C}_{2} \mathrm{C}(\mathrm{OO} \bullet) \mathrm{CC} \rightarrow \mathrm{TS} 28 \rightarrow \mathrm{C}_{2} \mathrm{C}(\mathrm{OOH}) \mathrm{CC} \bullet$
$\mathrm{C}_{2} \mathrm{C}(\mathrm{OO} \cdot) \mathrm{CC} \rightarrow \mathrm{TS} 29 \rightarrow \mathrm{C}_{2} \cdot \mathrm{C}(\mathrm{OOH}) \mathrm{CC}$
$\mathrm{C}_{2} \mathrm{C}(\mathrm{OO} \cdot) \mathrm{CC} \rightarrow \mathrm{TS} 30 \rightarrow \mathrm{C}_{2} \mathrm{C}(\mathrm{OOH}) \mathrm{C} \cdot \mathrm{C}$

This class of reaction represents intramolecular, endothermic, transfer of an H atom from a OH or $\mathrm{CH}_{3}$ group to the peroxy oxygen radical site via a 5 or 6 -member ring transition state (includes the H atom). The cleaving $\mathrm{O}-\mathrm{H}$ bond stretches to $1.35 \sim 1.365$ $\AA$ from $0.96 \AA$, and the cleaving $\mathrm{C}-\mathrm{H}$ bond stretches to $(1.34,1.37) \sim 1.42 \AA$ from $1.09 \AA$, and the forming $\mathrm{OO}-\mathrm{H}$ bond length is $1.08 \sim 1.14(1.20,1.25) \AA$, which is longer than the $\mathrm{OO}-\mathrm{H}$ bond of $0.97 \AA$.

## Epoxide formation:

$\mathrm{C}_{2} \mathrm{C}(\mathrm{OOH}) \mathrm{CC} \bullet \mathrm{TS} 31 \rightarrow \mathrm{C}_{2} \mathrm{CyCOCC}+\mathrm{OH}$
In this reaction, the carbon radical in the $-\mathrm{CH}_{2} \bullet$ group attacks the carbon bonded peroxy oxygen to form 4-member ring transition state, while the weak $\mathrm{RO}-\mathrm{OH}$ bond is breaking. The cleaving $\mathrm{O}-\mathrm{O}$ bond length is $1.67 \AA$ and the forming $\mathrm{C}-\mathrm{O}$ bond length is $1.99 \AA$.

## $\mathbf{H O}_{2}$ group elimination ( $\beta$-scission):

$\mathrm{C}_{2} \mathrm{C}(\mathrm{OOH}) \mathrm{C} \cdot \mathrm{OH} \rightarrow \mathrm{TS} 18 \rightarrow \mathrm{C}_{2} \mathrm{C}=\mathrm{COH}+\mathrm{HO}_{2}$
$\mathrm{C}_{2} \cdot \mathrm{C}(\mathrm{OOH}) \mathrm{COH} \rightarrow \mathrm{TS} 21 \rightarrow \mathrm{C}=\mathrm{C}(\mathrm{C}) \mathrm{COH}+\mathrm{HO}_{2}$
$\mathrm{C}_{2} \mathrm{C}(\mathrm{OOH}) \mathrm{C} \cdot \mathrm{C} \rightarrow \mathrm{TS} 32 \rightarrow \mathrm{C}_{2} \mathrm{C}=\mathrm{CC}+\mathrm{HO}_{2}$
$\mathrm{C}_{2} \cdot \mathrm{C}(\mathrm{OOH}) \mathrm{CC} \rightarrow \mathrm{TS} 35 \rightarrow \mathrm{C}=\mathrm{C}(\mathrm{C}) \mathrm{CC}+\mathrm{HO}_{2}$
This reaction type represents the elimination (beta scission) of a $\mathrm{HO}_{2}$ radical from a hydroperoxide alkyl radical with olefin formation in the carbon backbone. The cleaving $\mathrm{C}-\mathrm{O}$ bond length is $1.94 \sim 1.99 \AA$, the forming $\mathrm{O}-\mathrm{OH}$ bond decreases from 1.46 to $1.40 \sim 1.42 \AA$ and the forming $\mathrm{C}=\mathrm{C}$ bond length is $1.38 \sim 1.39 \AA$ in the transition states.

## Concerted $\mathrm{HO}_{2}$ elimination:

$\mathrm{C}_{2} \mathrm{C}(\mathrm{OO} \cdot) \mathrm{COH} \rightarrow \mathrm{TS} 19 \rightarrow \mathrm{C} 2 \mathrm{C}=\mathrm{COH}+\mathrm{HO}_{2}$
$\mathrm{C}_{2} \mathrm{C}(\mathrm{OO} \cdot) \mathrm{COH} \rightarrow \mathrm{TS} 20 \rightarrow \mathrm{C}=\mathrm{C}(\mathrm{C}) \mathrm{COH}+\mathrm{HO}_{2}$
$\mathrm{C}_{2} \mathrm{C}(\mathrm{OO} \cdot) \mathrm{CC} \rightarrow \mathrm{TS} 33 \rightarrow \mathrm{C}=\mathrm{C}(\mathrm{C}) \mathrm{CC}+\mathrm{HO}_{2}$
$\mathrm{C}_{2} \mathrm{C}(\mathrm{OO} \cdot) \mathrm{CC} \rightarrow \mathrm{TS} 34 \rightarrow \mathrm{C}_{2} \mathrm{C}=\mathrm{CC}+\mathrm{HO}_{2}$
This reaction class represents a concerted elimination of $\mathrm{HO}_{2}$ radical from its alkyl peroxy parent to form an olefin. The cleaving $\mathrm{C}-\mathrm{O}$ and $\mathrm{C}-\mathrm{H}$ bond lengths are $2.28 \sim 2.31 \AA$ and $1.340 \sim 1.36 \AA$ respectively; and the forming $\mathrm{C}=\mathrm{C}$ and $\mathrm{O}-\mathrm{O}$ bond lengths are $1.39 \sim 1.51 \AA$ and $1.28 \AA$.

## Alkyl group elimination:

$\mathrm{C}_{2} \mathrm{C}(\mathrm{O} \cdot) \mathrm{COOH} \rightarrow \mathrm{TS} 24 \rightarrow \mathrm{C}_{2} \mathrm{C}=\mathrm{O}+\mathrm{CH}_{2} \mathrm{O}+\mathrm{OH}$
$\mathrm{C}_{2} \mathrm{C}(\mathrm{O} \bullet) \mathrm{COOH} \rightarrow \mathrm{TS} 25 \rightarrow \mathrm{CC}(=\mathrm{O}) \mathrm{COOH}+\mathrm{CH}_{3}$
$\mathrm{C}_{2} \cdot \mathrm{C}(\mathrm{OH}) \mathrm{COOH} \rightarrow \mathrm{TS} 26 \rightarrow \mathrm{C}=\mathrm{C}(\mathrm{C}) \mathrm{OH}+\mathrm{CH}_{2} \mathrm{O}+\mathrm{OH}$
This type of reaction represents an alkyl group or oxy-alkyl group leaving (perpendicular) from a near planar ethylene structure. For methyl dissociation in TS25, the $\mathrm{C}-\mathrm{C}$ bond length stretches from $1.58 \AA$ to $2.17 \AA$, and the forming $\mathrm{C}=\mathrm{O}$ bond length is $1.24 \AA$ in the TS structure.

For the $\mathrm{C} \cdot \mathrm{H}_{2} \mathrm{OOH}$ (immediately dissociates to $\mathrm{CH}_{2} \mathrm{O}+\mathrm{OH}$ ) elimination in TS24 and TS26, the cleaving $\mathrm{C}-\mathrm{C}$ bond length in the leaving group stretches from $2.06 \sim 2.21$ $\AA$, and the $\mathrm{O}-\mathrm{O}$ bond length lengthens slightly from $1.45 \sim 1.47 \AA$.

### 5.4.2 Thermochemical Properties

The enthalpies of formation for reactants, intermediate and products are calculated by isodesmic reactions analysis or taken from available literature. The enthalpies of standard species used in isodesmic reaction analysis are listed in Table 5.1, and Appendix Table C. 3 lists the calculated reaction enthalpies and $\Delta H_{f}^{o} 298$ values for the species in above oxidation systems at the three calculation levels. The average $\Delta H_{f}^{o} 298$ values from highlevel CBS-Q calculations are used for the kinetic model.

Enthalpies of formation for transition states are calculated by using the $\Delta H_{\mathrm{f}}{ }^{\circ}{ }_{298}$ values of stable radical adducts plus difference of total energies between the radical adducts and the transition states. The enthalpies of 21 transition states in the three isobutene adduct oxidation systems determined at the three different levels are listed in Table 5.2.

${ }^{2}$ Units in kcal $\mathrm{mol}^{-1}$.

Contributions from vibrational, translational, external rotational, and electronic degeneracy to $S^{\circ}{ }_{298}$ and $C_{p}(T)$ 's are calculated by statistical mechanics, and the contributions from internal rotations are replaced with values from previous work ${ }^{142}$ by evaluation of similar internal rotations. Table C. 4 lists the thermochemical properties of reactants, transition states, intermediates, and products in the reaction systems calculated by this work.

### 5.4.3 Analysis for Chemical Activation Reactions

5.4.3.1 $\mathbf{C}_{2} \mathbf{C} \cdot \mathbf{C O H}+\mathbf{O}_{2}$. The potential energy diagram for the $\mathrm{C}_{2} \mathrm{C} \cdot \mathrm{COH}+\mathrm{O}_{2}$ reaction system calculated at the CBS-Q level is shown in Figure 5.1. The reaction channels for the energized adduct $\left[\mathrm{C}_{2} \mathrm{C}(\mathrm{OO} \cdot) \mathrm{COH}\right]^{*}$ include dissociation back to reactants, stabilization to $\mathrm{C}_{2} \mathrm{C}(\mathrm{OO} \cdot) \mathrm{COH}$, several isomerizations followed by dissociation to products, and the concerted $\mathrm{HO}_{2}$ elimination reaction. The $\mathrm{C}_{2} \mathrm{C} \cdot \mathrm{COH}$ radical $\left(\Delta H_{\mathrm{f}}{ }^{\circ} 298=-\right.$ $22.22 \mathrm{kcal} \mathrm{mol}^{-1}$ ) reacts with $\mathrm{O}_{2}$ to form a chemically activated peroxy adduct $\mathrm{C}_{2} \mathrm{C}(\mathrm{OO} \cdot) \mathrm{COH}^{*}$ with a $40.49 \mathrm{kcal} \mathrm{mol}^{-1}$ well depth. This well depth allows the energized
peroxy adduct with sufficient energy to react over the barriers of two different concerted $\mathrm{HO}_{2}$ elimination paths and three H atom transfer isomerization reactions, followed by the isomers dissociation before stabilization. The three isomerization reactions for $\mathrm{C}_{2} \mathrm{C}(\mathrm{OO} \cdot) \mathrm{COH}$ adduct are: (1) hydrogen transfer from the hydroxyl group to the peroxy radical site via six-member ring $\operatorname{TS} 14\left(E_{a}=21.88 \mathrm{kcal} \mathrm{mol}^{-1}\right)$ to form a $\mathrm{C}_{2} \mathrm{C}(\mathrm{OOH}) \mathrm{CH}_{2} \mathrm{O} \cdot\left(\Delta H_{f}{ }^{\circ}{ }_{298}=-43.52 \mathrm{kcal} \mathrm{mol}^{-1}\right) ;$ (2) H atom transfer from a methyl via five-member ring TS15 $\left(E_{a}=35.46 \mathrm{kcal} \mathrm{mol}^{-1}\right)$ to form a $\mathrm{C}_{2} \bullet \mathrm{C}(\mathrm{OOH}) \mathrm{COH}\left(\Delta H_{f}{ }^{\circ}{ }_{298}=-\right.$ $46.68 \mathrm{kcal} \mathrm{mol}^{-1}$ ); (3) H atom transfer from the alcohol carbon via five-member ring $\operatorname{TS16}\left(E_{a}=28.41 \mathrm{kcal} \mathrm{mol}^{-1}\right)$ to form a C ${ }_{2} \mathrm{C}(\mathrm{OOH}) \mathrm{C} \cdot \mathrm{OH}\left(\Delta H_{f}{ }^{\circ}{ }_{298}=-49.16 \mathrm{kcal} \mathrm{mol}^{-1}\right)$.

Figure 5.1 Potential energy diagram for $\mathrm{C}_{2} \mathrm{C} \cdot \mathrm{COH}+\mathrm{O}_{2}$ reaction system.

The concerted $\mathrm{HO}_{2}$ elimination reactions for $\mathrm{C}_{2} \mathrm{C}(\mathrm{OO} \bullet) \mathrm{COH}$ adduct are: (1) via five-member ring TS19 $\left(E a=-31.93 \mathrm{kcal} \mathrm{mol}^{-1}\right)$ to $\mathrm{C}=\mathrm{C}(\mathrm{C}) \mathrm{COH}+\mathrm{HO}_{2}$; (2) via fivemember ring TS20 $\left(\mathrm{Ea}=-31.98 \mathrm{kcal} \mathrm{mol}^{-1}\right)$ to $\mathrm{C}_{2} \mathrm{C}=\mathrm{COH}+\mathrm{HO}_{2}$.

The forming alkoxy $\mathrm{C}_{2} \mathrm{C}(\mathrm{OOH}) \mathrm{CH}_{2} \mathrm{O}$ • isomer will undergo $\beta$-scission via TS17 $\left(E_{a}=6.15 \mathrm{kcal} \mathrm{mol}^{-1}\right)$ and rapidly decompose to acetone, formaldehyde, and OH radical. The resulting hydroperoxide-alkyl radicals will also undergo $\beta$-scissions $\left(\mathrm{HO}_{2}\right.$ elimination) to form vinyl alcohols plus $\mathrm{HO}_{2}$. The $\mathrm{C}_{2} \mathrm{C}(\mathrm{OOH}) \mathrm{C} \cdot \mathrm{OH}$ isomer dissociates to $\mathrm{C}_{2} \mathrm{C}=\mathrm{COH}+\mathrm{HO}_{2}$ via $\operatorname{TS} 18\left(E_{a}=11.65 \mathrm{kcal} \mathrm{mol}^{-1}\right)$, and $\mathrm{C}_{2} \cdot \mathrm{C}(\mathrm{OOH}) \mathrm{COH}$ isomer dissociates to $\mathrm{C}_{2} \mathrm{C}=\mathrm{COH}+\mathrm{HO}_{2}$ via $\operatorname{TS} 21\left(E_{a}=15.67 \mathrm{kcal} \mathrm{mol}^{-1}\right)$. The concerted elimination of $\mathrm{HO}_{2}$ radical from the peroxy $\mathrm{C}_{2} \mathrm{C}(\mathrm{OO} \bullet) \mathrm{COH}$ adduct also results in these same two vinyl alcohols.

Figure 5.2 Calculated temperature dependent rate constants for chemical activated $\mathrm{C}_{2} \mathrm{C} \cdot \mathrm{COH}+\mathrm{O}_{2}$ system at $\mathrm{P}=0.1 \mathrm{~atm}$,

The high-pressure limit rate constants from canonical transition state theory for $\mathrm{C}_{2} \mathrm{C} \cdot \mathrm{COH}+\mathrm{O}_{2}$ system are fitted by three parameters $A_{\infty}, n$, and $E_{\mathrm{a}}$ over temperature range from 298 to $2000 \mathrm{~K}, k_{\infty}=A T^{n} \exp \left(-E_{\alpha} / R T\right)$, by THERMKIN code. ${ }^{72}$ The input and output kinetic parameters for QRRK and Master equation analysis are listed in Table C.5.

The calculated pressure dependent rate constants for the chemical activation product channels of $\mathrm{C}_{2} \mathrm{C} \cdot \mathrm{COH}+\mathrm{O}_{2}$ vs temperature at $\mathrm{P}=0.1$ atm are presented in Figure 5.2. This figure shows that the dominant product-channel for $\mathrm{C}_{2} \mathrm{C} \cdot \mathrm{COH}+\mathrm{O}_{2}$ is stabilization to $\mathrm{C}_{2} \mathrm{C}(\mathrm{OO} \cdot) \mathrm{COH}$ below 700 K and dissociation back to $\mathrm{C}_{2} \mathrm{C} \cdot \mathrm{COH}+\mathrm{O}_{2}$ becomes the dominant channel when temperature is over 700 K . Dissociation to $\mathrm{C}_{2} \mathrm{C}=\mathrm{O}$ $+\mathrm{CH}_{2} \mathrm{O}+\mathrm{OH}$ is the more important product channel relative to the channels generating $\mathrm{HO}_{2}$ and vinyl alcohols.

Figure 5.3 Calculated pressure dependent rate constants for chemical activated $\mathrm{C}_{2} \mathrm{C} \cdot \mathrm{COH}+\mathrm{O}_{2}$ system at $\mathrm{T}=700 \mathrm{~K}$.

Figure 5.3 illustrates the pressure dependent rate constants of the chemically activated reactions at 700 K . The stabilization to the $\mathrm{C}_{2} \mathrm{C}(\mathrm{OO} \cdot) \mathrm{COH}$ is a dominant channel when pressure is over 0.1 atm at 700 K , and when pressure is lower than 0.1 atm , the dissociation back to $\mathrm{C}_{2} \mathrm{C} \cdot \mathrm{COH}+\mathrm{O}_{2}$ becomes the dominant channel.
5.4.3.2 $\mathbf{C}_{3} \cdot \mathbf{C O H}+\mathbf{O}_{2}$. The potential energy surface for the $\mathrm{C}_{3} \cdot \mathrm{COH}+\mathrm{O}_{2}$ reaction system calculated at the CBS-Q level is shown in Figure 5.4. The $\mathrm{C}_{3} \cdot \mathrm{COH}$ radical reacts with $\mathrm{O}_{2}$ to form a peroxy $\mathrm{C}_{2} \mathrm{C}(\mathrm{OH}) \mathrm{COO} \cdot$ adduct with a $37.64 \mathrm{kcal} \mathrm{mol}^{-1}$ well depth. Reaction channels for the energized adduct $\left[\mathrm{C}_{2} \mathrm{C}(\mathrm{OH}) \mathrm{COO} \cdot\right]^{*}$ include dissociation back to reactants, stabilization to $\mathrm{C}_{2} \mathrm{C}(\mathrm{OH}) \mathrm{COO}$ •, isomerization (hydrogen shift) via two different transition states to produce two hydroperoxide isomers: TS22 ( $E_{a}=22.81 \mathrm{kcal}$ $\left.\mathrm{mol}^{-1}\right)$ to $\mathrm{C}_{2} \mathrm{C}(\mathrm{O} \cdot) \mathrm{COOH}\left(\Delta H_{f}{ }^{\circ}{ }_{298}=-41.30 \mathrm{kcal} \mathrm{mol}^{-1}\right), \mathrm{TS} 23\left(E_{a}=26.71 \mathrm{kcal} \mathrm{mol}^{-1}\right)$ to $\mathrm{C}_{2} \cdot \mathrm{C}(\mathrm{OH}) \mathrm{COOH}\left(\Delta H_{f}{ }^{\circ}{ }_{298}=-44.27 \mathrm{kcal} \mathrm{mol}{ }^{-1}\right)$. The resulting alkoxy isomer $\mathrm{C}_{2} \mathrm{C}(\mathrm{O} \cdot) \mathrm{COOH}$ dissociates to $\mathrm{C}_{2} \mathrm{C}=\mathrm{O}+\mathrm{CH}_{2} \mathrm{O}+\mathrm{OH}$ via $\mathrm{TS} 24\left(E_{a}=9.31 \mathrm{kcal} \mathrm{mol}^{-1}\right)$, also dissociates to $\mathrm{CH}_{3}+\mathrm{CC}(=\mathrm{O}) \mathrm{COOH}$ via $\operatorname{TS} 25\left(E_{a}=12.94 \mathrm{kcal} \mathrm{mol}^{-1}\right)$. The forming hydroperoxide alkyl radicals will undergo dissociations to vinyl alcohol or vinyl hydroperoxide. The stable vinyl hydroperoxide product will also undergo homolytic cleavage of the weak $\mathrm{O}-\mathrm{O}$ bond in the peroxide moiety to generate OH and vinyl alkoxy species.

The high-pressure limit rate constants for $\mathrm{C}_{3} \cdot \mathrm{COH}+\mathrm{O}_{2}$ system as shown above are fitted by three parameters $A_{\infty}, n$, and $E_{\mathrm{a}}$ over temperature range from 298 to 2000 K . The input and output kinetic parameters for QRRK and Master equation analysis for this system are listed in Table C.6.

Unit: $\mathrm{kcal} / \mathrm{mol}$
Figure 5.4 Potential energy diagram for $\mathrm{C}_{3} \cdot \mathrm{COH}+\mathrm{O}_{2}$ reaction system.

The chemical activation calculated pressure dependent rate constants for the product channels of $\mathrm{C}_{3} \cdot \mathrm{COH}+\mathrm{O}_{2}$ versus temperature at 0.1 atm are shown in Figure 5.5. It shows that the dominant product is stabilization to $\mathrm{C}_{2}(\mathrm{COH}) \mathrm{COO} \cdot$ below 700 K , and dissociation back to $\mathrm{C}_{3} \cdot \mathrm{COH}+\mathrm{O}_{2}$ becomes the dominant channel when temperature is over 700 K . The reaction channel involving H -shift and dissociation to $\mathrm{C}_{2} \mathrm{C}=\mathrm{O}+\mathrm{CH}_{2} \mathrm{O}+$ OH is the most important new product channel.

Figure 5.6 illustrates the pressure dependent rate constants of the chemically activated reaction at 700 K . The stabilization to $\mathrm{C}_{2}(\mathrm{COH}) \mathrm{COO} \cdot$ is a dominant channel when pressure is over 0.1 atm at 700 K , and when pressure is lower than 0.1 atm , the dissociation back to $\mathrm{C}_{3} \cdot \mathrm{COH}+\mathrm{O}_{2}$ becomes the dominant channel.

Figure 5.5 Calculated temperature dependent rate constants for chemical activated $\mathrm{C}_{3} \cdot \mathrm{COH}+\mathrm{O}_{2}$ system at $\mathrm{P}=0.1 \mathrm{~atm}$ 。

Figure 5.6 Calculated pressure dependent rate constants for chemical activated $\mathrm{C}_{3} \cdot \mathrm{COH}$ $+\mathrm{O}_{2}$ system at $\mathrm{T}=700 \mathrm{~K}$.
5.4.3.3 $\mathrm{C}_{2} \mathbf{C} \cdot \mathrm{CC}+\mathrm{O}_{2}$. The potential energy diagram for the reactions of $\mathrm{C}_{3} \cdot \mathrm{CC}+\mathrm{O}_{2}$ calculated at the CBS-Q level is shown in Figure 7. A number of the reaction channels for $\left[\mathrm{C}_{2} \mathrm{C}(\mathrm{OO} \cdot) \mathrm{CC}\right]^{*}$ adduct are similar to those of $\left[\mathrm{C}_{2} \mathrm{C}(\mathrm{OO} \cdot) \mathrm{COH}\right]^{*}$ adduct in Figure 1 due to the similarity between the two adduct structures. The $\Delta H_{\mathrm{f}}{ }^{\circ}{ }_{298}$ value of $\mathrm{C}_{2} \mathrm{C} \cdot \mathrm{CC}$ radical is adopted from Tsang et al. ${ }^{55}, 6.7 \mathrm{kcal} \mathrm{mol}^{-1}$, and this results a well depth of $40.28 \mathrm{kcal} \mathrm{mol}^{-1}$ for $\mathrm{C}_{3} \cdot \mathrm{CC}+\mathrm{O}_{2}$; it shows good agreement with the well depth of $\mathrm{C}_{2} \mathrm{C} \cdot \mathrm{COH}+\mathrm{O}_{2}$ as shown above. Chen and Bozzelli ${ }^{102}$ calculated the well depth of tertbutyl radical $+\mathrm{O}_{2}$ to be $36.88 \mathrm{kcal} \mathrm{mol}^{-1}$ at the CBS-q//MP2(full)/6-31 $\mathrm{G}(\mathrm{d}, \mathrm{p})$ level, and Knyazev et al. ${ }^{126}$ reported this well depth as $36.52 \mathrm{kcal} \mathrm{mol}^{-1}$ from the third-law of treatment of the temperature dependencies of equilibrium constants.

Figure 5.7 Potential energy diagram for $\mathrm{C}_{2} \mathrm{C} \cdot \mathrm{CC}+\mathrm{O}_{2}$ reaction system.

As those of the other peroxy radicals reaction paths, the energized $\left[\mathrm{C}_{2} \mathrm{C}(\mathrm{OO} \cdot) \mathrm{CC}\right]^{*}$ adduct include dissociation to reactants, stabilization, concerted $\mathrm{HO}_{2}$
eliminations to products or isomerizations followed by dissociations to products. The important hydrogen transfer isomerization reactions are: (1) six-member ring TS28 ( $E_{a}=$ $\left.24.28 \mathrm{kcal} \mathrm{mol}^{-1}\right)$ to form $\mathrm{C}_{2} \mathrm{C}(\mathrm{OOH}) \mathrm{CC} \cdot\left(\Delta H_{f}{ }^{\circ}{ }_{298}=-14.48 \mathrm{kcal} \mathrm{mol}^{-1}\right)$; (2) five-member ring TS29 $\left(E_{a}=33.31 \mathrm{kcal} \mathrm{mol}^{-1}\right)$ to form $\mathrm{C}_{2} \cdot \mathrm{C}(\mathrm{OOH}) \mathrm{CC}\left(\Delta H_{f}{ }^{\circ}{ }_{298}=-12.58 \mathrm{kcal} \mathrm{mol}^{-1}\right)$; (3) five-member ring $\operatorname{TS} 30\left(E_{a}=33.08 \mathrm{kcal} \mathrm{mol}^{-1}\right)$ to form $\mathrm{C}_{2} \mathrm{C}(\mathrm{OOH}) \mathrm{C} \cdot \mathrm{C}\left(\Delta H_{f}{ }^{\circ}{ }_{298}=-\right.$ $16.63 \mathrm{kcal} \mathrm{mol}^{-1}$ ). The concerted $\mathrm{HO}_{2}$ elimination reactions are: (1) TS 33 ( $E a=29.54$ $\left.\mathrm{kcal} \mathrm{mol}{ }^{-1}\right)$ to $\mathrm{C}=\mathrm{C}(\mathrm{C}) \mathrm{CC}+\mathrm{HO}_{2}$; (2) $\mathrm{TS} 34\left(E a=29.82 \mathrm{kcal} \mathrm{mol}^{-1}\right)$ to $\mathrm{C}_{2} \mathrm{C}=\mathrm{CC}+\mathrm{HO}_{2}$.

The hydroperoxide alky radicals formed by hydrogen transfer reactions will undergo dissociation to form alkene plus $\mathrm{HO}_{2}$ and epoxide plus OH . The $\mathrm{C}_{2} \mathrm{C}(\mathrm{OOH}) \mathrm{CC} \bullet$ isomer dissociates to $\mathrm{C}_{2} \mathrm{CyCOCC}+\mathrm{CH}_{2} \mathrm{O}+\mathrm{OH}$ via $\mathrm{TS} 31\left(E_{a}=17.58\right)$, the $\mathrm{C}_{2} \mathrm{C}(\mathrm{OOH}) \mathrm{C} \cdot \mathrm{C}$ isomer dissociates to $\mathrm{C}_{2} \mathrm{C}=\mathrm{CC}+\mathrm{HO}_{2}$ via $\mathrm{TS} 32\left(E_{a}=11.98\right)$, and the $\mathrm{C}_{2} \cdot \mathrm{C}(\mathrm{OOH}) \mathrm{CC}$ isomer dissociates to $\mathrm{C}_{2} \mathrm{C}=\mathrm{CC}+\mathrm{HO}_{2}$ via TS35 $\left(E_{a}=13.61 \mathrm{kcal} \mathrm{mol}^{-1}\right)$.

The high-pressure limit rate constants for this $\mathrm{C}_{2} \mathrm{C} \cdot \mathrm{CC}+\mathrm{O}_{2}$ system, fitted by three parameters $A_{\infty}, n$, and $E_{\mathrm{a}}$ over temperature range from 298 to 2000 K , along with the input and output kinetic parameters for QRRK and Master equation analysis are listed in Table C.7.

The calculated pressure dependent rate constants for the product channels of $\mathrm{C}_{2} \mathrm{C} \cdot \mathrm{CC}+\mathrm{O}_{2}$ vs. temperature at $\mathrm{P}=0.1 \mathrm{~atm}$ are illustrated in Figure 5.8. The dominant product-channel is stabilization to $\mathrm{C}_{2} \mathrm{C}(\mathrm{OO} \cdot) \mathrm{CC}$ below 500 K and dissociation back to $\mathrm{C}_{2} \mathrm{C} \cdot \mathrm{CC}+\mathrm{O}_{2}$ becomes dominant when temperature is over 500 K . The channels concerted eliminations of $\mathrm{HO}_{2}$ forming conjugate alkene are the most important product channels. Figure 5.9 illustrates the pressure dependence for the rate constants of the chemically activated reactions at 700 K . The dissociation back to $\mathrm{C}_{2} \mathrm{C} \cdot \mathrm{CC}+\mathrm{O}_{2}$ is the
dominant channel at almost all the pressures, and the stabilization to the $\mathrm{C}_{2} \mathrm{C}(\mathrm{OO} \cdot) \mathrm{CC}$ is the next dominant.

Figure 5.8 Calculated temperature dependent rate constants for chemical activated $\mathrm{C}_{2} \mathrm{C} \cdot \mathrm{CC}+\mathrm{O}_{2}$ system at $\mathrm{P}=0.1 \mathrm{~atm}$.

Figure 5.9 Calculated pressure dependent rate constants for chemical activated $\mathrm{C}_{2} \mathrm{C} \cdot \mathrm{CC}$ $+\mathrm{O}_{2}$ system at $\mathrm{T}=700 \mathrm{~K}$.

### 5.4.4 Comparison of Model and Experiment

A detailed reaction mechanism (314 reactions, 126 species) for this neopentyl oxidation system is assembled in Table C.8, and the CHEMKIN II interpreter and integrator (version 3.1) ${ }^{140}$ is used to model the experimental $\mathrm{HO}_{2}$ formation profile for reaction time range $0 \sim 40 \mathrm{~ms}, 673 \mathrm{~K}$, and 59.3 torr. Abstraction reactions of $\mathrm{O}, \mathrm{OH}, \mathrm{HO}_{2}$, and $\mathrm{R} \cdot$ radicals are taken from evaluated literature. A procedure from Dean and Bozzelli ${ }^{141}$ is used to estimate abstraction rate constants by $\mathrm{H}, \mathrm{O}, \mathrm{OH}$, and $\mathrm{CH}_{3}$ radicals when no literature data are available.

Figure 5.10 Comparison of the present model with the experimental $\mathrm{HO}_{2}$ measurements of Taatjes et al. ${ }^{2}$

Figure 5.10 illustrates the time dependence of $\mathrm{HO}_{2}$ radical formation profile predicted by our model compared with the experimental data published by Taajes et al. ${ }^{103}$ The experiment was performed at 673 K , and the typical concentration are reported as: $\left[\mathrm{Cl}_{2}\right]=2 \times 10^{15}$ molecule $\mathrm{cm}^{-3},[\mathrm{Cl}]_{0}=2 \times 10^{15}$ molecule $\mathrm{cm}^{-3},\left[\right.$ neo- $\left.\mathrm{C}_{5} \mathrm{H}_{12}\right]=1 \times 10^{15}$ molecule $\mathrm{cm}^{-3},\left[\mathrm{O}_{2}\right]=6.7 \times 10^{16} \sim 6.0 \times 10^{17}$ molecule $\mathrm{cm}^{-3}$, with balance He up to a total density of $8.6 \times 10^{17}$ molecule $\mathrm{cm}^{-3}$. The green solid dot curve in Figure 5.10 represents our model for the $\mathrm{HO}_{2}$ formation profile at the higher oxygen concentration, $\mathrm{O}_{2}=6.0$ $\times 10^{17}$ molecule $\mathrm{cm}^{-3}$; it shows good agreement with experimental data of Taajes et al. Figure 5.11 illustrates the predicted time dependence of the $\mathrm{HO}_{2}$ radical compared with experimental data at the lower oxygen concentration, $\mathrm{O}_{2}=6.7 \times 10^{16}$ molecule $\mathrm{cm}^{-3}$; it shows good agreement with experimental data also.

Figure 5.11 Comparison of the present model with the experimental $\mathrm{HO}_{2}$ measurements of Taatjes et al. ${ }^{2}$

The unique molecular structure of neopentane eliminates the reaction path for formation of $\mathrm{C}_{5}$ conjugate alkene plus $\mathrm{HO}_{2}$ in the low temperature oxidation reactions, so the formation of $\mathrm{HO}_{2}$ must be attributed to its secondary reactions. A sensitivity analysis by using CHEMKIN (version 3.6.1) ${ }^{148}$ on the $\mathrm{HO}_{2}$ at the experimental condition $(\mathrm{T}=673$ $\mathrm{K}, \mathrm{P}=59.3$ torr, $\left[\mathrm{O}_{2}\right]=6.0 \times 10^{17}$ molecule $\mathrm{cm}^{-3}$ ) at the reaction time of $5,10,2030$ milliseconds is illustrated in Figure 5.12.

Figure 5.12 Sensitivity analysis on $\mathrm{HO}_{2}$ formation at $\mathrm{T}=673 \mathrm{~K}, \mathrm{P}=59.3$ torr, and $\left[\mathrm{O}_{2}\right]$ $=6.0 \times 10^{17}$ molecule $\mathrm{cm}^{-3}$.

Figure 5.12 shows that neopentyl peroxy radical self-reaction which generates neopentoxy radical plus $\mathrm{O}_{2}$ is the most sensitive for $\mathrm{HO}_{2}$ formation before 7 milliseconds. This is because that the neopentoxy radical will rapidly decompose to formaldehyde plus t-butyl radical which reacts with $\mathrm{O}_{2}$ to form $\mathrm{HO}_{2}$ by $\mathrm{HO}_{2}$ elimination path, which is impossible in $\mathrm{C}_{3} \mathrm{CC} \cdot+\mathrm{O}_{2}$ reaction system. Another important channel for $\mathrm{HO}_{2}$ formation
is OH reaction with 3,3-dimethyloxetane that is a main product for neopentyl radical oxidation $\left(\mathrm{C}_{2} \mathrm{CyCCOC}+\mathrm{OH} \rightarrow \mathrm{C}_{2} \mathrm{CyCCOC} \bullet+\mathrm{H}_{2} \mathrm{O}\right),{ }^{142}$ since the resulting radical will undergo ring opening to generate $\mathrm{HO}_{2}$ precursors such as $\mathrm{HC} \cdot \mathrm{O}$ and $\mathrm{CH}_{2} \mathrm{O}\left(\mathrm{C}_{2} \mathrm{CyCCOC} \bullet\right.$ $\left.\rightarrow \mathrm{C}_{2} \mathrm{C}=\mathrm{C}+\mathrm{HC} \cdot \mathrm{O}\right)$. The next sensitive channel for $\mathrm{HO}_{2}$ formation is OH abstraction of H atoms from neopentane radical $\left(\mathrm{C}_{3} \mathrm{CC}+\mathrm{OH} \rightarrow \mathrm{C}_{3} \mathrm{CC} \bullet+\mathrm{H}_{2} \mathrm{O}\right)$. Other reactions pathways responsible for the formation of $\mathrm{HO}_{2}$ are: $\mathrm{C}_{2} \mathrm{CC}(\mathrm{OOH}) \mathrm{CHO} \rightarrow$ $\mathrm{C}_{2} \mathrm{C}(\mathrm{CHO}) \mathrm{CH}_{2} \mathrm{O} \cdot+\mathrm{OH}$, which is responsible for chain branching and results in $\mathrm{HO}_{2}$ precursors; $\left(\mathrm{C}_{2} \mathrm{C}(\mathrm{CHO}) \mathrm{CH}_{2} \mathrm{O} \bullet \rightarrow \mathrm{C}_{2} \mathrm{C} \cdot \mathrm{CHO}+\mathrm{CH}_{2} \mathrm{O} ; \mathrm{C}_{2} \mathrm{C} \cdot \mathrm{CHO} \rightarrow \mathrm{C}=\mathrm{CC}+\mathrm{HCO}\right)$; $\mathrm{C}_{3} \mathrm{CCOO} \bullet+\mathrm{OH} \rightarrow \mathrm{HO}_{2}+\mathrm{C}_{3} \mathrm{CCO} \cdot$ as reported by Taatjes et al.; $\mathrm{H}+\mathrm{O}_{2}+\mathrm{M} \rightarrow \mathrm{HO}_{2}+$ $\mathrm{M} ; \mathrm{CH}_{2} \mathrm{O}+\mathrm{OH} \rightarrow \mathrm{H}_{2} \mathrm{O}+\mathrm{HC} \cdot \mathrm{O}$, and $\mathrm{C}_{2} \mathrm{C}=\mathrm{C}+\mathrm{OH} \rightarrow \mathrm{C}_{2} \mathrm{C} \cdot \mathrm{COH}$. These reactions are responsible for either direct formation of $\mathrm{HO}_{2}$, or the intermediates formation producing $\mathrm{HO}_{2}$. A typical intermediate is $\mathrm{HC} \cdot \mathrm{O}$, which reacts with $\mathrm{O}_{2}$ to forming $\mathrm{HO}_{2}$ plus $\mathrm{CO} .{ }^{149}$

The $\mathrm{HO}_{2}+\mathrm{OH} \rightarrow \mathrm{O}_{2}+\mathrm{H}_{2} \mathrm{O}$ reaction is indicated to be the most sensitive channel for the loss of $\mathrm{HO}_{2}$, and the neopentyl peroxy radical self-reaction which generates 2,2dimethylpropanal and 2,2-dimethylpropanol plus $\mathrm{O}_{2}$ is also sensitive. Other reactions paths sensitive for the loss of $\mathrm{HO}_{2}$ are: $\mathrm{HO}_{2}+\mathrm{HO}_{2} \rightarrow \mathrm{O}_{2}+\mathrm{H}_{2} \mathrm{O}_{2}, \mathrm{C}_{3} \mathrm{CCHO}+\mathrm{OH} \rightarrow$ $\mathrm{C}_{3} \mathrm{CC} \cdot=\mathrm{O}+\mathrm{H}_{2} \mathrm{O}, \mathrm{C}_{3} \mathrm{CCHO}+\mathrm{O}_{2} \rightarrow \mathrm{C}_{3} \mathrm{CC} \cdot=\mathrm{O}+\mathrm{HO}_{2}, \mathrm{HO}_{2}+\mathrm{H} \rightarrow \mathrm{OH}+\mathrm{OH}$.

### 5.5 Summary

The potential energy surfaces on the reaction systems of 2-hydroxy-1,1-dimethylethyl, 2-hydroxy-2-methylpropyl, and 1,1-dimethylpropyl radicals plus $\mathrm{O}_{2}$ and thermochemical properties of the species in these reaction systems are calculated based on ab initio CBS$Q$ and density functional theories. A mechanism describing reaction paths and kinetic
parameters for these oxidation reaction systems incorporating the mechanism in Chapter 4 are developed to model the experimental $\mathrm{HO}_{2}$ formation profiles. The kinetic parameters for intermediate and product formation channels of above systems are calculated versus temperature and pressure. Several reactions are predicted to be important for $\mathrm{HO}_{2}$ formation profile.

## CHAPTER 6

## THERMOCHEMICAL AND KINETIC ANALYSIS OF 2-METHYLBENZYL RADICAL OXIDATION REACTIONS

### 6.1 Background

Aromatic compounds are an important component of anthropogenic emissions from incomplete combustion and other evaporative emissions from solvents and fuels. Photochemical oxidation of aromatic hydrocarbons, such as benzene, toluene, and xylenes, is an important component in the chemistry of the reactive hydrocarbons in the atmosphere. ${ }^{150}$

Several reaction mechanisms have been proposed for interpretation of experimental laboratory and smog chamber photooxidation data. ${ }^{150-152}$ Emdee et al. ${ }^{153}$ studied the oxidation of o-xylene by flow reactor measurement at about 1150 K , and they proposed reaction pathways for oxidation of o-xylene at high temperature. They reported that ortho-xylene has higher reactivity compared with meta-xylene and para-xylene.

The reactions of the radicals from ortho xylene with $\mathrm{O}_{2}$ are important at low and intermediate temperature oxidations. A partial reaction mechanism for the 2methylbenzyl radical $+\mathrm{O}_{2}$ system is outlined in the scheme 1 . In this study, partial elementary reactions, energy well depths, and absolute rate constants for 2-methylbenzyl radical reactions with molecular oxygen are initially determined with computational chemistry at density functional levels. The reaction of 2-methylbenzyl radical (from ortho-xylene) with $\mathrm{O}_{2}$ is shown to have a more energetically favorable path for peroxy radical isomerization compared with its isomers: 3-methyl and 4-methyl - benzyl radicals. The resonance form of 2-methylbenzyl radical with radical site in benzene ring, can also
react with $\mathrm{O}_{2}$, but the adduct formed in this reaction has a low barrier to reverse reaction ( $18.2 \mathrm{kcal} \mathrm{mol}^{-1}$ ) and $\mathrm{O}_{2}$ will mostly add to the methyl group.

## Scheme 1

### 6.2 Results and Discussion

### 6.2.1 Thermochemical Properties

The geometries of reactants, important intermediates, transition states and products in ortho-xylene radical $+\mathrm{O}_{2}$ system are optimized using PM3 MOPAC ${ }^{84}$ calculations, followed by optimizations and frequency calculations at the B3LYP/6-31G(d,p) level using the Gaussian 98 program. ${ }^{32}$ The optimized geometry parameters of adduct ortho-
$\mathrm{C}_{6} \mathrm{H}_{4}\left(\mathrm{CH}_{3}\right) \mathrm{CH}_{2} \mathrm{OO}$ - and six transition states are shown in Appendix Table D.1; the corresponding vibrational frequencies and moments of inertia are listed in Table D.2.

The optimized structure parameters are used to obtain total electronic energies at the B3LYP/6-311++G(3df,2p) level. Vibrational frequencies are scaled by 0.9806 as recommended by Scott et al. ${ }^{42}$ for zero-point vibrational energies and thermal energies.

Enthalpies of formation for reactants, intermediates, and products are calculated using isodesmic working reaction analysis. Table D. 3 lists the isodesmic reactions, reaction enthalpies and calculated $\Delta H_{f}^{o} 298$ values for the important species in 2 methylbenzyl $+\mathrm{O}_{2}$ system at two DFT calculation levels. In our previous study, the calculated $\Delta H_{f}^{o} 298$ values from the DFT calculations were shown good agreement with the higher-level ab initio CBS-Q//B3 results. ${ }^{142}$ The $\Delta H_{\mathrm{f}}{ }^{\circ} 298$ values for ortho$\mathrm{C}_{6} \mathrm{H}_{4}\left(\mathrm{CH}_{3}\right) \mathrm{CH}_{2} \mathrm{OO} \bullet$, ortho- $\mathrm{C}_{6} \mathrm{H}_{4}\left(\mathrm{CH}_{2} \mathrm{OOH}\right) \mathrm{CH}_{2} \bullet$, and ortho- $\mathrm{C}_{6} \mathrm{H}_{4}\left(\mathrm{CH}_{2} \mathrm{OOH}\right) \mathrm{CH}_{2} \mathrm{OO} \bullet$ are calculated as $19.83,24.13$, and $5.81 \mathrm{kcal} \mathrm{mol}^{-1}$ at the B3LYP/6-311++G(3df,2p) level.

Enthalpies for transition states are calculated by using the $\Delta H_{\mathrm{f}}{ }^{\circ} 298$ value of stable adduct plus the difference of total energy between adduct and transition state. In this study, the barriers for transition states are also calculated at the KMLYP/6-311+G(d,p) level, since KMLYP method ${ }^{154}$ is reported to accurately predict transition state barriers with smaller errors than B3LYP ${ }^{155}$, BHandHLYP, and G2. ${ }^{156}$ KMLYP/6-311+G(d,p) calculation are preformed for geometry optimization and vibrational frequencies. Transition state barriers are corrected by zero-point energies, while the enthalpy of reaction are adjusted for thermal corrections at 298 K . Zero-point energies and thermal corrections for KMLYP are obtained using un-scaled harmonic frequencies since transition state barriers are slightly affected by scaling factor. The reaction enthalpies for
seven transition states in 2-methylbenzyl $+\mathrm{O}_{2}$ system determined at the B3LYP/6$31 \mathrm{G}(\mathrm{d}, \mathrm{p})$, B3LYP/6-311++G(3df,2p), KMLYP/6-311+G(d,p) levels are listed in Table 6.1. The reaction enthalpies show good agreement at the three calculation levels. The data calculated at the B3LYP/6-311++G(3df,2p) are used to calculate rate constants.

Table 6.1 Reaction Enthalpies ${ }^{\text {a }}$

The entropies and heat capacity contributions from vibrational, translational, and external rotational contributions are calculated using statistical mechanics based on the vibrational frequencies and structures obtained from the density functional study. Potential barriers for the internal rotations are calculated at the B3LYP/6-31G(d,p) level, and hindered rotational contributions to entropies and heat capacities are calculated by using direct integration over energy levels of the internal rotational potentials.

### 6.2.2 Analysis of Internal Rotors

The calculated internal rotational potentials on the $\mathrm{C}_{\text {benzene }}-\mathrm{CH}_{3}$ bond in ortho$\mathrm{C}_{6} \mathrm{H}_{4}\left(\mathrm{CH}_{3}\right) \mathrm{CH}_{2} \mathrm{OO} \bullet$ is shown in Figure 6.1. It shows the normal 3-fold rotational barrier for methyl rotation on the $\mathrm{C}_{\text {benzene }}-\mathrm{CH}_{3}$ bond; this radical has the lowest energy when the dihedral $\angle \mathrm{H}(13)-\mathrm{C}(7)-\mathrm{C}(6)-\mathrm{C}(5)=0$, this is due to the intramolecular interaction between
the peroxy $\mathrm{O}(18)$ atom and $\mathrm{H}(15)$ atom in the methyl group (see structure in Appendix Table D.1), since the intramolecular distance between these two atoms is $2.65 \AA$ which is near to the sum of the van der Waals radii of H and $\mathrm{O}(2.6 \AA)$.

Figure 6.1 The internal rotational potentials on the $\mathrm{C}_{\text {benzene }}-\mathrm{CH}_{3}$ bond in ortho$\mathrm{C}_{6} \mathrm{H}_{4}\left(\mathrm{CH}_{3}\right) \mathrm{CH}_{2} \mathrm{OO} \bullet$.

The calculated rotational potentials for the $\mathrm{CH}_{2} \mathrm{COO} \bullet$ group rotation on the C $\mathrm{C}_{\text {benzene }}$ bond in ortho- $\mathrm{C}_{6} \mathrm{H}_{4}\left(\mathrm{CH}_{3}\right) \mathrm{CH}_{2} \mathrm{OO} \bullet$ is shown in Figure 6.2. This radical has the highest energy when the peroxy central oxygen is near cis to the benzene bond of the ortho link (the dihedral $\angle \mathrm{C}(6)-\mathrm{C}(1)-\mathrm{C}(8)-\mathrm{O}(18)=-24.8^{\circ}$, and the dihedral $\angle \mathrm{C}(1)-\mathrm{C}(8)-$ $\left.\mathrm{O}(18)-\mathrm{O}(19)=174.5^{\circ}\right)$. The high energy is mostly due to steric effect between $\mathrm{CH}_{2} \mathrm{OO} \cdot$ group and the methyl group, as the carbon - oxygen bond is pointed toward the methyl group. The second maxima corresponds to the structure with the peroxy central oxygen pointed away from the methyl and again near cis with the benzene ring, the dihedral
$\angle \mathrm{C}(7)-\mathrm{C}(6)-\mathrm{C}(1)-\mathrm{C}(8)=0^{\circ}, \angle \mathrm{C}(1)-\mathrm{C}(8)-\mathrm{O}(18)-\mathrm{O}(19)=180^{\circ}$. This orientation of the $\mathrm{CH}_{2} \mathrm{OO} \bullet$ group reduces the steric effect, and has a slightly reduced energy.

Figure 6.2 The rotational potentials on the $\mathrm{C}-\mathrm{C}_{\text {benzene }}$ bond in ortho$\mathrm{C}_{6} \mathrm{H}_{4}\left(\mathrm{CH}_{3}\right) \mathrm{CH}_{2} \mathrm{OO} \bullet$.

Figure 6.3 shows the calculated rotational potentials for OO• group rotation on the $\mathrm{R}-\mathrm{OO} \bullet$ bond in ortho- $\mathrm{C}_{6} \mathrm{H}_{4}\left(\mathrm{CH}_{3}\right) \mathrm{CH}_{2} \mathrm{OO} \bullet$ radical. It shows three-fold barrier that is highly non-symmetric with barrier height about $3.62 \mathrm{kcal} \mathrm{mol}^{-1}$.

The calculated rotational potentials for the OH group rotation on the $\mathrm{RO}-\mathrm{OH}$ bond in ortho $-\mathrm{C}_{6} \mathrm{H}_{4}\left(\mathrm{CH}_{2} \mathrm{OOH}\right) \mathrm{CH}_{2} \bullet$ radical is illustrated in Figure 6.4 ; the $5.65 \mathrm{kcal} \mathrm{mol}^{-}$ ${ }^{1}$ barrier height is typical of published data on the $\mathrm{RO}-\mathrm{OH}$ bond rotations. ${ }^{77,135}$

Figure 6.3 The rotational potentials on the $\mathrm{R}-\mathrm{OO} \bullet$ bond in ortho- $\mathrm{C}_{6} \mathrm{H}_{4}\left(\mathrm{CH}_{3}\right) \mathrm{CH}_{2} \mathrm{OO} \bullet$ radical.

Figure 6.4 The calculated rotational potentials on the RO-OH bond in ortho$\mathrm{C}_{6} \mathrm{H}_{4}\left(\mathrm{CH}_{2} \mathrm{OOH}\right) \mathrm{CH}_{2} \bullet$ radical.

### 6.2.3 Reactivity of Ortho-, Meta, and Para-Xylenes

To compare the reactivity of ortho-, meta-, para-oxylene radicals, the activation energy for isomerization of the corresponding xylene peroxy radicals are calculated at the B3LYP/6-311++G(3df,2p) level. The activation energy for 2-methylbenzyl peroxy radical isomerization to 2-methylbenzyl methyl-hydroperoxide via a 7-member ring transition state is $21.21 \mathrm{kcal} \mathrm{mol}^{-1}$, but 3-methylbenzyl peroxy radical needs 60.05 kcal $\mathrm{mol}^{-1}$ activation energy via a 8-member ring transition state, and 4-methylbenzyl methylhydroperoxide needs $73.62 \mathrm{kcal} \mathrm{mol}^{-1}$ activation energy via a 9 -member ring transition state, to isomerize to the corresponding methylbenzyl methyl-hydroperoxides. The high barriers for meta- and pare-xylene radicals are because the meta-, para interactions in corresponding TS structures bend benzene rings out of a planar position (the dihedral angle for four carbon in benzene ring those involved in transition state are $25^{\circ}$ and $32^{\circ}$ ), therefore, results in some loss of aromaticity. The activation energies for the isomerization of meta-, para-oxylene of peroxy radicals are also listed in Table 6.1. These data shows ortho-xylene is the most reactive compared with its meta-xylene and paraxylene isomers, and it shows agreement with the experimental results. ${ }^{153}$

### 6.2.4 Kinetic Analysis of 2-Methylbenzyl $+\mathrm{O}_{2}$ System

A potential energy diagram for the 2-methylbenzyl $+\mathrm{O}_{2}$ reaction system calculated at the B3LYP/6-311++G(3df,2p) level is shown in Figure 6.5. The 2-methylbenzyl radical reacts with $\mathrm{O}_{2}$ to form a chemically activated ortho $-\mathrm{C}_{6} \mathrm{H}_{4}\left(\mathrm{CH}_{3}\right) \mathrm{CH}_{2} \mathrm{OO} \bullet *$ adduct, which can be stabilized, dissociate back to reactants, or isomerize via three different paths. TS1 is a H atom transfer to the peroxy radical forming 2-methylbenzyl methyl-hydroperoxide (ortho- $\mathrm{C}_{6} \mathrm{H}_{4}\left(\mathrm{CH}_{2} \mathrm{OOH}\right) \mathrm{CH}_{2} \bullet$ ) with activation energy of $21.21 \mathrm{kcal} \mathrm{mol}^{-1}$. This barrier is much lower than those of 3-methylbenzyl and 4-methylbenzyl radicals since the ortho interaction between the H atom and peroxy oxygen atom in the TS structure keep the benzene ring almost planar. This is a near thermoneutral reaction - abstraction of a benzyl H atom and formation of a hydroperoxide through a 7-member ring transition state. The barrier of $21 \mathrm{kcal} \mathrm{mol}^{-1}$ is similar to the well depth of $\mathrm{O}_{2}$ addition to orthoxylene radical.

Figure 6.5 Potential energy diagram for the 2-methylbenzyl $+\mathrm{O}_{2}$ reaction system.

The forming 2-methylbenzyl methyl-hydroperoxide will undergo dissociation via TS5 to produce major product isobenzofuran with barrier of $21.85 \mathrm{kcal} / \mathrm{mol}$. In TS2 the peroxy radical attacks the ipso aromatic carbon (carbon bonded to the $-\mathrm{CH}_{2} \mathrm{OO} \bullet$ group, via 4 -member ring transition state with a barrier of $34.91 \mathrm{kcal} \mathrm{mol}^{-1}$. This breaks the aromatic resonance and forms a bicylcic molecule with a cyclohexadienyl radical and a peroxide ring. This bicyclic can undergo reverse reaction or cleave a carbon - carbon bond to form ortho phenoxy radical and formaldehyde, $\mathrm{CH}_{2} \mathrm{O}$.

In TS3 the peroxy oxygen abstracts an H atom from an ortho position on the in benzene ring via 6 -member ring transition state with a barrier of $30.90 \mathrm{kcal} \mathrm{mol}^{-1}$. The peroxy ROO- H bond formed is only $86.5 \mathrm{kcal} \mathrm{mol}^{-1}$ and the phenyl- H bond cleaved is $113 \mathrm{kcal} \mathrm{mol}^{-1}$, thus the barrier is only $2.4 \mathrm{kcal} \mathrm{mol}^{-1}$ above the endothermicity. While the barrier of $30.9 \mathrm{kcal} \mathrm{mol}^{-1}$ is ca $10 \mathrm{kcal} \mathrm{mol}^{-1}$ above the energy of the initial xylene radical $+\mathrm{O}_{2}$ reactants, the reaction is important. It forms a phenyl radical, which reacts rapidly and is highly exoergic with $\mathrm{O}_{2}$. The main products from the methyl substituted phenyl + $\mathrm{O}_{2}$ reaction will be ring opening to $\mathrm{CO}+\mathrm{HC} \equiv \mathrm{CH}+\mathrm{CH}_{3}-\mathrm{C} \equiv \mathrm{C}+\mathrm{HC} \bullet \mathrm{O}$.

The reaction described as TS4 has the peroxy radical abstracting a H atom from the ipso (peroxy) carbon via a 4-member ring transition state to form an intermediate alkyl-hydroperoxide radical $(\mathrm{RC} \cdot \mathrm{OOH})$ that immediately dissociates via a $\beta$ scission reaction to form a strong carbonyl and cleave the weak $\mathrm{RO}-\mathrm{OH}$ bond. The resulting products are ortho $-\mathrm{C}_{6} \mathrm{H}_{4}\left(\mathrm{CH}_{3}\right) \mathrm{CH}(=\mathrm{O})+\mathrm{OH}$, but the 4 -member ring transition state results in a barrier of $38.21 \mathrm{kcal} \mathrm{mol}^{-1}$.

### 6.2.5 Reaction of Ortho- $\mathrm{C}_{6} \mathrm{H}_{4}\left(\mathrm{CH}_{2} \mathrm{OOH}\right) \mathrm{CH}_{\mathbf{2}} \bullet$ Isomer

Figure 6.6 shows the further oxidation reactions of the isomer, ortho$\mathrm{C}_{6} \mathrm{H}_{4}\left(\mathrm{CH}_{2} \mathrm{OOH}\right) \mathrm{CH}_{2} \bullet$, as calculated at the B3LYP/6-311++G(3df,2p) level. This isomer reacts with a second $\mathrm{O}_{2}$ to form a chemically activated ortho- $\mathrm{C}_{6} \mathrm{H}_{4}\left(\mathrm{CH}_{2} \mathrm{OOH}\right) \mathrm{CH}_{2} \mathrm{OO} \bullet *$ adduct, which can be stabilized or can isomerize and dissociate to new products.

TS6 has a 7 -member ring structure where the $\mathrm{C}_{6} \mathrm{H}_{4}\left(\mathrm{CH}_{2} \mathrm{OOH}\right) \mathrm{CH}_{2} \mathrm{OO}$ - peroxy radical abstracts a H atom from the $\mathrm{CH}_{2} \mathrm{OOH}$ carbon, with a barrier of $16.07 \mathrm{kcal} \mathrm{mol}^{-1}$, a $\mathrm{RC} \cdot \mathrm{OOH}$ moiety is formed, which as in the case of TS4 above, immediately dissociates to ortho-methyl-hydroperoxide benzylaldehyde (ortho- $\left.\mathrm{C}_{6} \mathrm{H}_{4}\left(\mathrm{CH}_{2} \mathrm{OOH}\right) \mathrm{CHO}\right)+\mathrm{OH}$.

Figure 6.6 Isomer ortho $-\mathrm{C}_{6} \mathrm{H}_{4}\left(\mathrm{CH}_{2} \mathrm{OOH}\right) \mathrm{CH}_{2} \bullet$ oxidation reaction system.

TS7 has a similar structure as that of TS3, in which the peroxy radical abstracts an H from an ortho position on the benzene ring. The barrier for TS7 is calculated to be $29.90 \mathrm{kcal} \mathrm{mol}^{-1}$. As above the phenyl radical formed will rapidly react with $\mathrm{O}_{2}$ and under go ring opening and dissociation to lower molecular weight products.

The stabilized ortho- $\mathrm{C}_{6} \mathrm{H}_{4}\left(\mathrm{CH}_{2} \mathrm{OOH}\right) \mathrm{CH}_{2} \mathrm{OO} \bullet$ adduct and stable ortho$\mathrm{C}_{6} \mathrm{H}_{4}\left(\mathrm{CH}_{2} \mathrm{OOH}\right) \mathrm{CHO}$ undergo homolytic cleavage of the weak $\mathrm{O}-\mathrm{O}$ bonds with the barrier of ca. $44 \mathrm{kcal} \mathrm{mol}^{-1}$. The ortho $-\mathrm{C}_{6} \mathrm{H}_{4}(\mathrm{CHO}) \mathrm{CH}_{2} \mathrm{O}$ • radical will then undergo unimolecular dissociation via TS8 to ortho $-\mathrm{C}_{6} \mathrm{H}_{4}(\mathrm{CHO})_{2}+\mathrm{H}$ with barrier of 21.59 kcal $\mathrm{mol}^{-1}$.

### 6.2.5 Kinetic Parameters

The high-pressure limit rate constants $\left(\mathrm{k}_{\infty}\right)$ for the chemically activated 2-methylbenzyl + $\mathrm{O}_{2}$ system are determined by canonical transition state theory using structural parameters and vibration frequencies. The high-pressure limit rate constants used in QRRK analysis are fitted by three parameters $A_{\infty}, \mathrm{n}$, and $E_{\mathrm{a}}$ over temperature range from 298 to 2000 K ; Lennard-Jones parameters, $\sigma$ (Angstroms) and $\varepsilon / \kappa$ (Kelvins), are estimated from tabulations, ${ }^{90}$ and these input data for QRRK analysis are listed in Table 6.2.

The calculated temperature dependent rate constants for 2-methylbenzyl $+\mathrm{O}_{2}$ reaction system at 1 atm from the QRRK combined with Master equation analysis are illustrated in Figure 6.7. The dominant product-channel is stabilization to ortho$\mathrm{C}_{6} \mathrm{H}_{4}\left(\mathrm{CH}_{3}\right) \mathrm{CH}_{2} \mathrm{OO}$ • below 800 K , and reverse reaction becomes dominant when temperature is above 800 K .

Table 6.2 Kinetic Parameters for QRRK in 2-Methylbenzyl Radical + $\mathrm{O}_{2}$ System

| reaction | $A\left(\mathrm{~s}^{-1}\right.$ or $\left.\mathrm{cm}^{3} \mathrm{~mol}^{-1} \mathrm{~s}^{-1}\right)$ | $\mathrm{s}^{-1}$ ) $n$ | $E_{a}\left(\right.$ kcal mol ${ }^{-1}$ ) |

$\overline{{ }^{\mathrm{a}} \text { Estimated from } \mathrm{C}_{2} \bullet \mathrm{C}=\mathrm{C}+\mathrm{O}_{2} \text { by Chen et al. }{ }^{128}{ }^{6.60} \text { From the principle of microscopic }}$ reversibility at 700 K

Figure 6.7 Rate constants for chemical activation reaction: $0-\mathrm{C}_{6} \mathrm{H}_{4}\left(\mathrm{CH}_{3}\right) \mathrm{CH}_{2} \bullet+\mathrm{O}_{2}$ at $\mathrm{P}=$ 1 atm.

Figure 6.8 Rate constants for chemical activation reaction: $\mathrm{o}-\mathrm{C}_{6} \mathrm{H}_{4}\left(\mathrm{CH}_{3}\right) \mathrm{CH}_{2} \bullet+\mathrm{O}_{2}$ at $\mathrm{T}=$ 1000 K .

Figure 6.8 shows the calculated rate constants vs. pressure for the chemically activated reaction 2-methylbenzyl $+\mathrm{O}_{2}$ at 1000 K ; it shows the rate constants for stabilization and isomerization channel are increased with increased pressure, but other reaction channels have no pressure dependence over $0.001 \sim 10 \mathrm{~atm}$.

The calculated temperature dependent dissociation rate constants for stabilized ortho- $\mathrm{C}_{6} \mathrm{H}_{4}\left(\mathrm{CH}_{3}\right) \mathrm{CH}_{2} \mathrm{OO} \bullet$ radical reaction system at 1 atm are illustrated in Figure 6.9. The dominant channel is reverse back to ortho- $\mathrm{C}_{6} \mathrm{H}_{4}\left(\mathrm{CH}_{3}\right) \mathrm{CH}_{2} \bullet+\mathrm{O}_{2}$ at all temperatures, and the next dominant channel is the preoxy radical isomerization to ortho$\mathrm{C}_{6} \mathrm{H}_{4}\left(\mathrm{CH}_{2} \mathrm{OOH}\right) \mathrm{CH}_{2} \bullet$ radical.

Figure 6.9 Rate constants for dissociation reaction: $\mathrm{o}-\mathrm{C}_{6} \mathrm{H}_{4}\left(\mathrm{CH}_{3}\right) \mathrm{CH}_{2} \mathrm{OO} \cdot$ at $\mathrm{P}=1 \mathrm{~atm}$.

Figure 6.10 Rate constants for chemical activation reaction: o- $\mathrm{C}_{6} \mathrm{H}_{4}\left(\mathrm{CH}_{2} \mathrm{OOH}\right) \mathrm{CH}_{2} \bullet+\mathrm{O}_{2}$ at $\mathrm{P}=1 \mathrm{~atm}$.

The calculated temperature dependent rate constants for $\mathrm{C}_{6} \mathrm{H}_{4}\left(\mathrm{CH}_{2} \mathrm{OOH}\right) \mathrm{CH}_{2} \bullet+$ $\mathrm{O}_{2}$ reaction system at 1 atm are showed in Figure 6.10. The dominant product-channel is stabilization to ortho $-\mathrm{C}_{6} \mathrm{H}_{4}\left(\mathrm{CH}_{2} \mathrm{OOH}\right) \mathrm{CH}_{2} \mathrm{OO}$ • below 700 K and reverse reaction dominates at the temperatures above 700 K .

### 6.3 Summary

Thermochemical properties for reactants, intermediates, products and transition states important in 2-methylbenzyl radical $+\mathrm{O}_{2}$ reaction system are calculated at the density functional levels. Potential barriers for the internal rotations are calculated at the B3LYP/6-31G(d,p) level. Potential energy surfaces are calculated at the DFT B3LYP/6$31 \mathrm{G}(\mathrm{d}, \mathrm{p})$ and $\mathrm{B} 3 \mathrm{LYP} / 6-311++\mathrm{G}(3 \mathrm{df}, 2 \mathrm{p})$ levels, and compared with the reaction enthalpies calculated at the KMLYP/6-311+G(d,p) level. Important initial product and intermediate channels in low temperature o-xylene oxidation system are stabilization, reverse dissociation, isomerization of the peroxy radical to the hydroperoxide isomer which dissociates to isobenzofuran plus OH . The intermediate stable products are predicted to be o-tolualdehyde, phthaladehyde, isobenzofuran, and o-xylylene.

## APPENDIX A

TABLES IN THE THERMOCHEMICAL AND KINETIC ANALYSIS OF CHLORINATED ALCOHOLS, HYDROPEROXIDES AND RADICALS

This appendix lists the geometrical parameters, reaction enthalpies, and calculated enthalpies of formation for chlorinated alcohols, alkyl hydroperoxides, and corresponding radicals, as discussed in Chapter 2 and Chapter 3.

## APPENDIX B

## TABLES IN THE THERMOCHEMICAL AND KINETIC ANALYSIS OF REACTION OF NEOPENTYL RADICAL WITH MOLECULAR OXYGEN

This appendix lists the geometrical parameters, harmonic vibrational frequencies, thermodynamic analysis and detailed reaction mechanism for reactions of neopentyl radical oxidation, as discussed in Chapter 4.

Table B. 1 Geometrical Parameters for Species in Neopentyl Oxidation System

## APPENDIX C

## TABLES IN THE THERMOCHEMICAL AND KINETIC ANALYSIS OF REACTIONS OF ISOBUTENE ADDUCTS OXIDATION

This appendix lists the geometrical parameters, harmonic vibrational frequencies, thermodynamic analysis and detailed reaction mechanism for reactions of isobutene adducts (2-Hydroxy-1,1-Dimethylethyl, 2-Hydroxy-2-

Methylpropyl, and 1,1-Dimethylpropyl radicals) oxidation, as discussed in Chapter 5.

## APPENDIX D <br> TABLES IN THE THERMOCHEMICAL AND KINETIC ANALYSIS ON REACTION OF 2-METHYLBENZYL RADICAL OXIDATION

This appendix lists the geometrical parameters, harmonic vibrational frequencies, isodesmic reaction analysis for calculation of enthalpy values on reaction of 2methylbenzyl radical oxidation, as discussed in Chapter 6.

[^0]:    ${ }^{a}$ Distance in Angstrom, Angles in Degree.

[^1]:    ${ }^{a}$ Reaction enthalpies include thermal correction and zero-point energy. Units in $\mathrm{kcal} / \mathrm{mol}$.
    ${ }^{\mathrm{b}}$ The deviation are between the isodesmic reactions (see text).
